Wishing to go a step further M. Mitscherlich sought to discover whether the rays usually considered characteristic of metals were produced by the metal itself as by its oxide. For this purpose it was necessary to avoid the reducing action of the flame. With this object he heated the combination to redness in a porcelain tube closed at each end with glass; and commenced by receiving on the spectro-scope the light emanating from the inside of the tube containing the combination partially reduced to vapour. This light being very feeble he placed a bright flame at the other extremity of the heated tube, allowing thus the rays furnished by the substance to be observable owing to their being reversed. M. Mitscherlich's experiments were chiefly with soda, sodium, chloride of sodium and carbonate of soda; sodium alone gave a spectrum under these circumstances. With all deference to the opinion of M. Mitscherlich, who is well known as an accurate and acute observer, we do not agree with the conclusions he draws from these experiments. He says that the result of these researches is that to the free metal alone are due its characteristic rays, and that if they are seen with its combinations, reduction takes place by the carbon and hydrogen of the flame. Very possibly this may be the case, indeed some recent researches about which we shall have more to say shortly, seem to prove that it is so, but we cannot admit that M. Mitscherlich's experiments prove anything except that the heat to which he submitted his porcelain tube was not sufficient to volatilize the contained soda salts. Sodium was the only substance which gave a spectrum under these circumstances, because it was the only body which could be volatilized at the temperature employed. To render the experiment worth anything the heat should have been raised sufficiently to render the other soda salts thoroughly gaseous, and then if their vapours, seen through the length of the tube, were unable to plough out the black line D from the continuous spectrum of the luminous flame, it might be regarded as evidence of what is attempted to be proved; but as the experiment at present stands it merely

shows that insufficient heat was employed. Granting, however, that further experiments would confirm M. Mitscherlich's opinion that the spectral rays belong to the metal in its pure and simple state, another deduction springs from the fact. That is that the solar atmosphere does not contain sufficient oxygen to oxidise all the sodium contained in it, and that all the metals having less affinity for oxygen than sodium are free; it may, moreover, be admitted that if in the solar atmosphere there exist metals combined with electro-negative elements in spite of the presence of free sodium their affinities are inverted at the high temperature of this atmosphere. Moreover, if the rays of certain metals are not observed it is impossible to be quite certain of their absence; for they may exist in a state of combination like chloride of potassium, which in the presence of some other bodies, as shown above, gives no spectrum.

A most ingenious barometer, for measuring small atmospheric disturbances, has recently been devised by Dr. Joule. It consists of a large glass carboy connected by a glass tube with a miniature gasometer, formed by inserting a small platinum crucible over a small vessel of water. The crucible is attached to the short end of a finely suspended lever, multiplying its motion six times. When the apparatus was raised two feet the index moved through one inch; hence he was able in serene weather to observe the effect corresponding to the elevation of less than one inch. The barometer is placed in a building, the slated roof of which affords, without perceptible draught, free communication with the external atmosphere. In this situation it was found that the slightest wind caused the index to oscillate, a gale occasioning oscillations of two inches, an increase of pressure being generally observed when the gusts took place. This barometer is undoubtedly very sensitive, and is highly spoken of amongst scientific circles in Manchester. It will however, of course, only show relative pressure, not absolute, as the indications would vary as much, or even more, by an increase or diminution of temperature. It would not be difficult we think to compensate it for temperature, and thus to render such a barometer an accurate measure of the height of the atmosphere as well as of its passing waves.

Critical Notices.

PRACTICAL ADVICE TO AMATEUR PHOTOGRAPHERS; or, the Direct Negative Process, v. Strengthening Positives. By HENRY MATHESON, eight years Principal Operator in the Photographic Department, Crystal Palace, Sydenham. London: JAMES HOW, Successor to G. Knight and Sons.

The author of the little work before us is a professional photographer of many years' standing, his experience, as he informs us, extending "from the old daguerreotyping times to the present of *cartes de visite*." It is almost impossible for an experienced practical man to write upon his art without saying something interesting and useful, and Mr. Matheson says much in his book which will well repay perusal.

The title of the book scarcely entirely conveys its character, for, whilst it contains much advice for amateurs, it is practically a manual for beginners, commencing with instructions for obtaining collodion positives and proceeding onwards to the production of prints on paper. Incidentally, in the course of his instructions, the author introduces what appears to be the great aim of the work, an argument in favour of simply iodized collodion, and a method of using iron development so as to secure negatives at one operation, as superior to the use of bromo-iodized collodion, and the necessity of using intensifying processes which he conceives it involves.

The author's predilections are very strongly in favour of what he terms the direct negative process, in which bromo-iodized collodions are, he states, "a delusion and a snare."

Mr. Sutton, who, as our readers know, has been the strong champion of simply iodized collodion against bromo-iodized collodion, has always insisted as one of the points of its excellence that it required the use of pure chemicals, simple and unsophisticated, the nitrate bath especially consisting only of pure nitrate of silver and water, without doctoring of any kind. Mr. Matheson insists on the addition of acetate of soda in the bath as a condition of success. As this is a point to which he attaches considerable importance, we will quote his remarks upon the subject:—

BEST CHEMICAL CONDITION OF BATH.—We have found that for a negative bath to give a film sufficiently sensitive, yet at the same time to develop dense enough for printing at once, and without re-developing or strengthening, or whatever it may be termed, a small quantity of *alkali*—masked, however, by a slight excess of some organic acid—is indispensable. To prove this position, let us examine the results we get from the formulae for bath and developing solutions which most beginners in photography are taught to use. Let us take the favourite one, which seems to be, pure nitrate of silver and distilled water, with a little iodide of some kind added to it (to prevent the silver entering away the iodide from the film of collodion), and perhaps a little alcohol or ether, or, may be, an infinitesimal dose of acetic or nitric acid. Practically, what is the result? Why, on developing the picture taken with an iodized collodion (which, we repeat, is best for negatives), and a neutral, or simple silver and water bath, it will be found that the picture appears struggling to get through a cloud of all sorts of photographic difficulties, in the shape of fog, veils, haze, streaks, comets, &c., &c., and the picture appears under-exposed. The remedy for this, say some, is a little acid—well, let us try—say, nitric. We try another glass, and what do we get? If sufficient is added to clear away the previous difficulties, we get another; for if developed with pyrogallic acid, the picture is certainly free from the previous defects, but the picture vanishes with them, and we only get the extreme high lights, and those so faint as to be totally useless for printing. With the iron developer the matter is very little better, besides the greater length of exposure necessary in the camera.

Suppose we had tried a little acetic acid instead, we should find the bath deteriorated in sensitiveness, without getting rid of our enemies.

Let us now try the system advised by the writer, starting with a neutral, or plain silver and water bath.

To a fifteen-ounce bath, of the strength of thirty-five grains to the ounce, let us add one or two grains of an alkali dissolved in a little distilled water; after well shaking this with the bath for a minute or two, the bath should be well filtered. After preparing a glass, and giving it the right exposure in the camera, what do we now find on developing? Positively nothing at all apparently. The film blackens instantaneously under the developer, and there is no picture to be seen, but we do see the character of the deposit is totally changed; instead of the previous greyish-laden line of the surface, we have, after the picture has been fixed and washed, a deposit of a brownish orange colour, and when held up to the light and looked through, the film appears of a brownish yellow, inclining in some places to a purple. The bath now evidently requires a little acid of some kind to prevent the spontaneous blackening of the film; but as the alkali was added to the bath to remove all traces of free nitric acid, it is evident that nitric acid cannot be used, or any other which would liberate it. We have tried various acids, but find none equal to acetic, which, for reasons too numerous to be mentioned here, we recommend as being the best. Acetic must be added very sparingly to the bath, just barely sufficient to mask the alkali and to develop clearly. Two or three drops are more than sufficient to neutralize the small portion of oxide of silver formed from the alkali.

As the strength of acetic acid is very subject to variation in different samples, and as it is not always possible, or convenient, to get pure caustic potash, soda, or other alkalies, it will be found much more certain if we take an acetate of any alkali, say acetate of soda (as the most conveniently obtained), because here acid and alkali are combined in equivalent proportions. To a fifteen-ounce bath add two or three grains of this salt, dissolved in half an ounce of distilled water; this will combine with the nitrate of silver when added to the bath, forming acetate of silver, which readily dissolves therein to the extent of nearly twenty grains to a pint. For this reason more than the two or three grains recommended may be added without injury, only that the proportion of acid which is to be added in addition will have to be increased in the same ratio, and will be found less manageable.

Supposing, then, we have added to a fifteen-ounce bath two grains of acetate of soda, we shall find, on developing a picture, the same spontaneous blackening of the film, provided there was no free nitric acid in the crystals of silver of which the bath was composed, as it very often happens there is a trace. Should there have been any free nitric acid in the crystals, it will perhaps be found not necessary to add any more acid, as the nitric acid may have liberated sufficient acetic acid from the acetate of silver by forming nitrate of the oxide of silver, and setting acetic acid free. Should, however, this not be the case, make a solution of a drop of pure nitric acid in an ounce of distilled water; add a drachm or two to the bath, occasionally trying a picture, until it develops satisfactorily.

It may be thought a paradox to add nitric acid, when we are trying to secure ourselves against the presence of this very acid; but it will be found that, although we could not use it to neutralize oxide of silver formed by the addition of alkali to the bath (as it would have been only bringing it back to its previous condition of a neutral nitrate), yet, in the case of the presence of an acetate, the effect is quite altered, as was shown by the description of the action of free nitric acid sometimes found in the bath, due to its being introduced in the crystals of some samples of silver.

No matter, however, how or by what method we introduce the acetate—whether by an alkali to be masked by acetic acid, or by the addition of an acetate (which is the mode we recommend), with a portion of its acid set free by the cautious introduction of a minute quantity of nitric acid—the change in the picture is marvellously satisfactory; for now, instead of a picture flat, and too faint for printing, we get an intensity which may be carried to opacity if desired, without any "re-developing," "convertlug," "blackening," &c., &c., with all their attendant risks, uncertainties, and vexations. The change in the colour of the negative is just as extraordinary—the surface appears, when viewed by reflected light, to show objects in almost their

natural colours; indeed, in the case of a landscape, we have often seen them have the effect of views when seen at sunset. This, although so far satisfactory, makes no difference as to its printing qualities, only that when we get negatives with this coloured surface we may be sure the bath is in good working order.

The developer recommended for use with this bath and simply iodized collodion is as follows:—protosulphate of iron, ten grains; glacial acetic acid, thirty minims; water, one ounce; a drop of the strongest liquor ammonia being added when the whole is mixed. If the negative be too dense, the proportion of ammonia is to be reduced; if too weak, increased.

The advantages claimed for the direct negative process, are that the process is simpler, the results are more under control, the exposure not much longer than with bromo-iodized collodion, and that the negatives are better and more vigorous.

We do not intend to enter here into a discussion of a subject we have so often treated, further than to state our conviction, that whilst Mr. Matheson invokes for his favourite process a fresh trial, he does not appear to us to have given the method now almost universally in use, with bromo-iodized collodion, by any means such a fair trial as is necessary for a discussion of its merits. We arrive at this conclusion as we peruse his book. In comparing, for instance, the simplicity of his own process with that now commonly used, it never seems to enter his calculations that negatives are frequently obtained by means of bromo-iodized collodion, with quite sufficient printing vigour, without any process of intensification. As to the comparative excellence of the two classes of negatives, we are scarcely surprised that he should prefer his own and speak of the rough granular looking deposit on the others; for, on examining his instructions for producing negatives with bromo-iodized collodion, we find, what he must pardon us for styling, a general slovenliness in the operations. He says, for instance, "a little old positive bath kept in a small bottle is a very convenient way of having at hand the silver used for blackening." Again, "the pyrogallie acid solution should be rather strong—say, ten grains to the ounce of water, controlled by a little citric acid—say, a lump the size of a horse bean to half a pint of solution." If he have been in the habit of using old silver bath charged with iodide of silver for intensifying, we do not wonder that the negatives have a granular surface; we cannot indorse either his recommendation to use citric acid by the "lump," nor his statement that citric acid gives a colour favourable for printing, as in truth the blue tint it confers readily permits the actinic rays to pass, and practically reduces the strength of the negative.

One of the methods given for intensifying is to pour over a fixed positive "a solution of bichloride of mercury either in alcohol or dilute hydrochloric acid; after the film has been properly acted upon to the satisfaction of the operator, wash off all traces of bichloride of mercury with water; then pour on a very weak solution of hyposulphite of soda, which will turn the deposit into an intense black." Now as bichloride of mercury is soluble in water to the extent of 30 grains to an ounce, a greater strength than it is desirable for photographers to use, the employment of either alcohol or dilute hydrochloric acid is unnecessary and mischievous, as the latter render the film rotten, and the former renders necessary an amount of washing which loosens the film, and thus causes one of the evils, the occasional loss of films, which he charges on the process generally. We might quote more to show that the writer either was not familiar with the process he condemns, or that he had practised it in a very slovenly fashion; but we have said enough on that subject.

In treating of his favourite direct negative process, Mr. Matheson is much more satisfactory, and for those who are wishful once more to try that method we can recommend him as a most satisfactory companion and guide. We must add, moreover, that he discusses the questions with the utmost candour, and straightforwardness, and fairness.

In the printing process he recommends an alkaline gold solution with a little more than two grains of bicarbonate of

soda to each grain of chloride of gold, which, he states, if kept three or four hours before use, tones perfectly, without any tendency to mealiness. It has the disadvantage of not keeping longer than that time. He recommends also the dangerous plan of using old hypo solutions, strengthened from time to time, in order to avoid loss of tone, in preference to the constant use of fresh solutions.

A chapter on Photography in Tropical Climates, based upon the author's own experience in India, is excellent, and only too short. It will be read with great interest by all who wish to practice the art in hot climates; many of the hints it contains may be noted with advantage for observance during the heat of summer in this country. The remarks on glass houses are, for the most part, thoroughly intelligent and to the purpose. The form of room recommended, of which a design is given, is one of the best we have seen. We should have preferred the side lights down to the ground, especially for eard portraiture; but with that exception we consider the room perfect. On another page we give the chapter in its entirety, and are enabled, by the courtesy of Mr. How, the publisher, to place the diagrams, illustrating what to avoid and what to build, before our readers.

ON THE ACTION OF PHOTOGRAPHIC VARNISHES UPON THE COLLODION FILM.

BY DR. D. VAN MONCKHOVEN.

It frequently occurs that the varnish completely removes the intensity of the image on the collodion. The aim of this short article is to point out the cause of this phenomenon, and to indicate a method of remedying it.

When a collodion plate, upon its removal from the camera, is covered with the developing solution, the image, as is well known, gradually appears. Many persons imagine that the image formed penetrates the film, but this is not the fact, for, upon examining the film on the back of the plate, we perceive that the iodide of silver remains perfectly white.

The luminous impression is confined to the surface of the sensitive film, and does not penetrate its substance; besides, the silver deposited by the developer superficially swells the fibres of the gun-cotton, and forms an image in relief.

The developed image may, therefore, be considered as formed of two films; the first, constituted by the pyroxyline and iodide of silver, unchanged; the second, by the metallic silver; some traces of iodide of silver, which, before the development, constituted the most superficial part of the film; and, lastly, a very small quantity of pyroxyline, the fibres of which are distended by the deposited silver.

Now we must not forget that gun-cotton is partially soluble in alcohol, benzine, and several other liquids, especially when they are thoroughly deprived of water. Anhydrous alcohol, at 42°, for example, dissolves a large proportion of pyroxyline, while alcohol at 40° dissolves only traces of it, and alcohol at 36° none at all.

Now, in the manufacture of varnish, it is necessary, in order to dissolve the resins which form their basis, to employ alcohol at 42°. What takes place, then, in making use of such a varnish? Why, it dissolves the superficial part of the collodion film, and the image is either wholly removed, or, as frequently happens, its intensity is greatly diminished. The first case is easily explained; the second is intelligible when we consider that the molecules of silver forming the image are at first spongy, then, suddenly, by the removal of the pyroxyline, reduced to the state of boil, which necessarily opposes fewer obstacles to the passage of the luminous rays. Not only spirit-varnish, but also those containing benzine frequently present this defect, and recently, M. Vidal, in employing the excellent varnish described by us some years ago, viz., amber, torrefied at 300° C. dissolved in benzine—informed M. Deltenre, the

manufacturer, of the fact that the varnish frequently deprived the negatives of their intensity.

At a recent meeting of the Photographic Society of London, Mr. Shadbolt explained the fact in question by the dissolving of the pyroxyline, while, on the other hand, Dr. Diamond and Mr. Wright maintained that the pyroxyline is not dissolved. We perceive that these two opinions are reconcilable. The pyroxyline is removed, but only in small quantity, and the pyroxyline remains, but only the film subjacent to the silver deposited by the developer, and that is the most considerable portion.

According to the explanation we have given of this phenomenon, it is easy to point out a remedy which shall protect the film from the varnish; it is sufficient, upon removal from the washing which follows the fixing, to cover the plate with a solution of gum-arabic, consisting of one drachm of pure gum dissolved in ten ounces of water. In this case, the liquid gum penetrates the superficial film which constitutes the image, and imprisons it, so to speak; and when, after it is dried, we cover the plate with alcohol or benzine varnish, no particle of gum-cotton can be dissolved, and, consequently, the negative loses some of its intensity.

I may add, that this process of a preliminary gumming is employed by many professional photographers, who have noticed the fact of loss of intensity by pure and simple varnishing.

In conclusion, I shall state that a varnish formed only of gum-arabic is bad, because the gum swells in summer, deriving humidity from the atmosphere, and sticks to the positive paper. The varnish of white lac is abandoned, because it must be applied warm; that of amber and chloroform is removed under friction of the finger—deficient, therefore, in hardness; that of benzoin is still worse; finally, there remains the formula we gave some years ago—*torrefied amber and benzine*—which, on the contrary, gives a very fine hard surface, and which does not adhere to the positive paper.—*Le Moniteur de la Photographie.*

RECOVERY OF GOLD AND SILVER FROM WASTE PHOTOGRAPHIC MATERIALS.

BY WILLIAM ENGLAND.*

GENTLEMEN,—It is scarcely necessary to remind you that, in all affairs of business, economy is one of the great objects held in view, either of labour, material, or time; and I think it behoves every one whose opportunities or experience enables him to arrive at facts which result in economy to make known those means. With this view, I propose to occupy your attention for a short time upon a subject which I think is important to all photographers, and most particularly to those whose business is extensive.

I will not try your patience by detailing a long and elaborate account of a number of experiments, with a view to arrive at the easiest methods of recovering the gold and silver from waste material; the few remarks to which I shall call your attention may be relied upon as being purely practical and simple, and I hope may prove of some service to those who have not been able to devote the time and attention necessary to ensure success.

I may here mention, that in the course of the past winter I have operated upon and recovered nearly *one thousand ounces* of metallic silver; in fact, during the dull, short days, when photographic operations are at a stand still, this is rather an agreeable, as well as useful occupation.

The materials we have to operate upon are too well known to need description. We will, therefore, take them in the following order:—

Firstly, Washings from the prints and all solutions that can be precipitated as chlorides.

Secondly, Hypo fixing baths, to which may be added the used-out toning-bath, &c.

Thirdly, Sensitive-paper cuttings, filters and any materials containing silver which can be reduced to ashes; and,

Lastly, Kaolin, which has been used for cleansing the sensitizing bath. This contains a large amount of nitrate.

I shall in the first part of this paper, speak of some of the methods of precipitating and preparing the sulphurets, chlorides, &c., ready for the furnace; and, in the second, the reduction of the same into the metallic state.

The first on our list are the chlorides. The method of precipitation with common salt is so well known that no mention is required, more than that the deposit should be well washed and thoroughly dried.

In recovering the metals from the hypo solutions, Mr. Hardwich recommends that it should be boiled for two or three hours in contact with zinc; other authorities recommend adding to the boiling solution hydrochloric acid. Neither of these methods is found in practice to answer well. With the first it is difficult to get rid of the whole of the zinc; and the second plan is objectionable on account of the large amount of sulphur precipitated with the silver and which gives considerable trouble in the process of reduction. Perhaps there is no better method than the one most commonly adopted, that of adding sulphide of potassium; but care should be taken not to add an excess. A simple way to avoid waste is to test as follows:—After the deposit has subsided test the liquor in a test-tube by dropping in a drop or two of sulphide solution; the result will show at a glance whether the whole of the silver and gold has been thrown down.

Now take another sample, and test with silver, to ascertain if an excess of sulphur has been added; if so, it would be advisable to throw in more of the fixing bath, and allow it to settle before drawing off. These experiments are necessary; for, if sufficient sulphide has not been used, of course the whole of the silver will not be precipitated; and should a large excess have been thrown in, a portion of the deposit would be redissolved, causing a waste.

The silvered paper may be conveniently burnt out in the open air in a sheet-iron box about 3 feet deep by 2 wide. Allow the burnt waste to smoulder for a considerable time, to burn off the charred matter; by so doing, it will take up less space in the crucible in reducing. It is a curious fact that these burnt ashes are very sensitive to light, changing from a light drab to a deep brown in a few minutes in sunshine, proving that the action of the fire in consuming the paper only fuses the chloride, instead of reducing it to metallic particles.

Kaolin, as may be supposed, cannot be readily melted in the furnace; therefore, in operating upon this material, we must proceed in a different manner. A simple and economical method is to place a pound or two in a stone pitcher, and pour in an equal quantity of nitric acid, containing about 25 per cent. of water, stirring well the while. Place the pitcher in a warm place for a few hours, and afterwards add a couple of quarts of water, stirring it well again. Allow the kaolin to settle, and draw off, repeating the operation several times, of course saving the liquid, from which the silver can be precipitated as chloride. Kaolin, treated in this way, may be used any number of times, provided the acid is well washed out.

I will now proceed to the second part of this paper—the reduction of the metals. A good furnace is, of course, indispensable. Black's answers very well; but it is too small to take a good-sized crucible. A furnace may be constructed of a simple form and very cheap with a few fire-bricks. A convenient size is about two feet deep by sixteen inches wide, with an ash-pit beneath. No door will be required, as it may be fed from the top. Half a dozen bricks, cemented together and bound round with an iron band, will form an excellent cover. This furnace should be built where a good draught can be obtained, as the success of our operations will much depend upon having a considerable heat. The

* Read at a meeting of the London Photographic Society, on Tuesday, May 5.

only other apparatus required is a few crucibles, usually called pots, a pair of long pincers, some fluxes, such as borax, carbonate of soda, carbonate of potash, and some nitre,

Now let us suppose everything ready to commence operations.

We will begin with the ashes from the paper, that being the simplest. Weigh out two 21bs. of ashes, to which add the same quantity of carbonate of soda and 1 lb. of carbonate of potash. Afterwards take a well dried crucible, and place it in the furnace, mouth downwards, and build up the fire around it. It is necessary to adopt this plan to prevent the pot splitting; or when, in our innocence, we fondly imagine our smelting operations to be complete, on looking in the pot we discover, not metal, but emptiness, and the silver in the ashes under the furnace. After the fire has burnt up, take out the crucible and place it in the right position, mouth upwards. Now fill it about three parts full with the mixture; again make up the fire to a good heat. After the contents of the pot have melted down, another lot may be added, again making up the fire to the greatest possible degree of heat, and in about an hour our operation will be complete, provided the fire has been properly attended to.

To economise time and material, the pot may be taken from the fire, and the contents poured into an iron ladle, the pot put back into the furnace, again filled up with more material, proceeding as before. On turning out the contents of the ladle, the silver will be found at the bottom of the flux.

In reducing chloride, a different method must be adopted. Mix carbonate of soda and potash in equal quantities, add one pound to one pound of chloride of silver, mix well, and throw into a red-hot crucible small portions at a time; for, if the whole were thrown in at once, the effervescence which ensues would boil over, and cause a considerable waste of silver. It is necessary in these operations to weigh out the materials, and after each one to compare results, to enable us to judge whether our experiment has been complete.

Chloride of silver will yield 75 per cent. of metal, paper ashes about 50 to 60 per cent.; but, of course, much will depend upon its freedom from impurities.

Sulphuret of silver and gold is much more difficult to reduce, on account of the large amount of sulphur in combination. After the precipitate has been thoroughly dried, it must be mixed with an equal weight of nitre, and thrown a little at a time into a red-hot crucible. An iron ladle will be necessary for this purpose. Care must be taken not to put in too large a quantity, or the combustion which takes place will drive the metal out of the pot. When the crucible is full, the fire must be made up, and a good heat maintained for about half an hour, after which the cover may be removed, and a portion of the flux taken out with an iron ladle, to make room for more material, and the same process repeated; after which more flux should be taken out and its place supplied with a small quantity of nitre and some carbonate of soda. This will ensure the whole of the sulphur being got rid of. The fire should now be continued for about a couple of hours.

On removing the crucible from the fire, should the experiment have been successful, the whole of the silver, in combination with the gold, will be found at the bottom of the pot.

The two metals may be readily separated by nitric acid, to which a little water has been added to assist the oxidation. The gold will be left in the state of a fine black powder, which must be carefully separated, and may be converted into chloride by nitro-muriatic in the usual way.

In these remarks, I have omitted many matters of detail, fearing to trespass too much upon your valuable time. I therefore thank you, gentlemen, for your kind attention; and should these observations prove of any practical value, or if there be any question I can answer, it will afford me much pleasure.

A SHORT LESSON IN PHOTOGRAPHY.—No. 13.*

THE pictures have been in the water upwards of twelve hours, and during this interval the water has been changed several times, so that by this process every trace of the hyposulphite of soda has been removed. In large photographic establishments an arrangement is made for washing the fixed prints which is supplied with fresh water from a stopcock connected with the water-works. This apparatus is so adjusted on pivots as to rise and fall like the beam of a pair of scales, and it is put in motion by the weight of the water itself. It consists, in the first place, of a trough of wood of any given appropriate length, as, for instance, three feet; its breadth may be one foot, and its height the same. It is divided into two compartments in the middle, and supported on pivots in the middle of the base-board about six inches above the table or shelf on which it rests; by this means it has an oscillating motion or play of about twelve inches at either end like a see-saw. This trough is placed so that the middle division is, when horizontal, immediately below the stopcock; but when one end is down and filled with water, and the other up and empty, it is evident that if the stopcock be open, the water will flow into the empty compartment until this sinks, which it will do when the other is empty. Each compartment is supplied with a syphon whose arch reaches to near a plane level with the top; the calibre of this syphon is somewhat greater than that of the ingress pipe furnished with the stopcock. Now when either end becomes filled with water, the latter will rise higher than the arch of the syphon, which will then be filled with water. The longer arm of the syphon passes through the end of each compartment and discharges the water from its corresponding end somewhat quicker than the water is supplied to the other end by the stopcock. By this arrangement one end becomes alternately light and heavy, and thus produces a constant oscillation of the whole trough up and down. The prints to be washed are placed in these troughs as soon as they leave the fixing bath, and are thus kept in motion and supplied with fresh water for any length of time. Such a machine is called the *self-acting photographic washing machine*. When prints are thus treated, an hour's washing will remove every trace of the hyposulphite of soda.

They are then taken out one by one and pinned by one corner to slips of wood on the side-walls of the room until they are thoroughly dry. Naturally they may be dried by artificial heat in chambers fitted up for the purpose.

How to Mount Card Pictures.

If four or more pictures are printed on the same piece of albumen paper, the whole piece may be brushed over with a solution of gum arabic and gelatine, or, what is still better, with a solution of patent starch or dextrine such as is used on the back of post-stamps. As soon as it is dry it is placed, with the starch side downwards, on a plate of glass. Then placing a mat with the proper-sized opening, or a piece of glass of the exact size and with accurately ground edges, over each card picture, the latter is neatly and carefully cut out with a sharp-pointed penknife. This act of cutting out the pictures requires considerable dexterity in pressing the plate and making the incision so that the terminal cut is a continuity of the commencement, and that the edge all round is clean and not dentated. A whetstone or hone is a very necessary appendage to the mounting table.

When the pictures are printed singly some artists cut them out before they are brushed over with the starch. In this case they are pasted immediately upon the mounts and passed soon afterwards through the glazing machine. In the former case either the surface of the mounts or the starched surface of the prints is made moist by passing over it a moderately wet sponge, and then the print is placed upon its appropriate position and pressed intimately by the motion of the rollers of the press.

* From *Humphrey's Journal*.

When the artist does not possess such a machine, the prints are brought as before upon the mounts after they have been starched or gummed, and then by placing over each picture a piece of clean writing paper larger than the print, and by holding the first and second finger far apart firmly upon its surface, the print is pressed upon the cardboard by rubbing the space between the two fingers with a burnishing tool or the smooth handle of a tooth-brush. The fingers then assume different positions until the whole print is thoroughly adhesive to the mounts.

When pictures are mounted in this way it is very necessary to remove all prominent particles of dust or sand from the starched surface, otherwise they will spoil the picture by producing similar prominences through the paper of the print.

What to do with the Clippings of Prints.

Spoiled prints, soiled sensitized paper, and the entings of pictures may as well be preserved as not; for the labour consists in simply placing them in some corner or box instead of throwing them away. As soon as the stock is very large, they may be burnt in a clean stove and the ashes collected. These ashes contain silver, oxide of silver, and other combinations of silver, together with the minerals in the paper, as, for instance, lime, &c. The ashes so constituted are pressed closely and firmly together into a Hessian crucible, then submitted to a powerful heat, and thus reduced. Or these ashes may be mixed with the refuse chloride of silver, dried, and then fused with an addition of about one-third their weight of either carbonate of soda or carbonate of potassa.

In large establishments the refuse silver salts, as well as the cuttings of paper, amount to quite a sum annually, and are frequently sold for reduction to parties who make it their business. Where such an opportunity presents itself, it is more advantageous to dispose of the unreduced refuse, than to perform the operation.

And now, dear card picture, I must take my leave, and wish you all the welcome and warm reception that a genial spirit can desire or is wont to meet with. Whether on a mission of love, of grief, or of municipal investigation, your presence is inferior alone to the reality. Is not this true? Witness the beaming smile on the countenance of the dying soldier on the banks of the Rappahannock, as he presses the beloved card for the last time to the last palpitation of his heart. Witness the gentle tears of the widowed mother when she compares the lineaments of her child with the noble features of one that fell in the defence of his country. Witness the easy recognition of an arrant villain by the scrutinizing eye of an adept, glancing from fact to fiction, from the corporeal frame to the pictorial representation. A card picture is a reality! and if the Roman poet had lived in the age of actinic drawing, he would have continued those verses, which Penelope addressed to her lingering Ulysses, which stand thus:—

“Hanc tua Penelope lento tibi mittit, Ulysse.
Nil mihi rescribas ut tamen, ipse veni.”

by saying:—

“If it should happen you cannot, then do the next best in your power,
Send me your picture on card drawn by the rays of the sun.”

COPYRIGHT IN ENGRAVINGS AND PHOTOGRAPHS.

Mr. GAMBART'S industry and perseverance in defending his copyright property have been crowned with remarkable success. Our readers will remember that, some few months since, an action was tried before Mr. Justice Willes, which had been brought by Mr. Gambart for piracy of his two copyright engravings, “The Light of the World,” and “The Horse Fair,” by making and selling small *photographic* copies made from prints taken from these engravings. Mr. Gambart obtained the verdict, with ten pounds damages; but, upon a question of law being raised, whether copying the prints in question by means of photography and selling such copies,

is prohibited within the meaning of the Engraving Acts, the learned Judge reserved leave to the defendant to take the opinion of the Court of Common Pleas upon that point. On Saturday last, the question was argued before the Lord Chief Justice Erle, and three other of the Judges, who were unanimously of opinion that Mr. Gambart was entitled to retain the verdict he had obtained.

This decision is of unusual interest and importance to a considerable number of persons. It remedies the mischief of which the print-publishers have so long and bitterly complained—inasmuch as it clearly establishes that making, selling, or publishing any photographic copy of a copyright engraving or lithograph of any description, if done without the consent of the proprietor of such copyright, renders the offender liable to the pains and penalties defined by the Engraving Acts. The decision thus directly affects the interests of every painter, engraver, photographer, print and photograph seller throughout the United Kingdom. Taken in conjunction with the Act of last session, which, it should be remembered, for the first time created a copyright in pictures and drawings, the decision gives a security to the proprietors of copyrights in British engravings, which they have never hitherto enjoyed. The increased value of pictures and engravings, resulting from that security against the piracy of artistic property will, we trust, be productive of the most beneficial results in the arts of designing and engraving.

It may be useful, at this time especially, to remind artists and the purchasers of their works of the protection the law now enables them to acquire for their copyright property. Under the Act of last session, the exclusive copyright in any *original* painting, drawing, and photograph may be effectually protected in every case where such work was not sold or disposed of before the 29th of July, 1862. If a work has been executed upon commission, then the copyright belongs to the employer, and not to the artist. If, on the other hand, it was not executed upon commission, then the copyright is the property of the artist; but such copyright will become public property, unless at or before the time when such artist first sells or disposes of his work he agrees, in writing, with the purchaser thereof, as to the sale or reservation of the copyright. If the artist reserves it, the agreement must be *signed* by the purchaser; and if the latter is to have the copyright, then the agreement must be *signed* by the artist or by his agent.

But in no case can any legal proceedings for the infringement of such copyright be maintained against a pirate unless that copyright has been *registered* at Stationers' Hall before the act of piracy complained of has been committed. Hence the necessity of registering every original painting, drawing, and photograph as soon as possible. It only remains to add, upon this part of the subject, that by the agreement above mentioned an artist may effectually reserve his copyright for all purposes of *engraving*, where the bargain is that the purchaser shall have the copyright, by stipulating in the agreement that the purchaser shall grant the artist or his nominee an *exclusive license* to engrave the work in question.

To acquire copyright under the Engraving Acts, an engraving or lithograph in which such right is claimed must have been actually made in some part of the United Kingdom; and the name of the proprietor of the copyright and date of first publication of the print must be truly stated upon the plate or block, &c., and printed on *every* print taken from such plate, &c.

All engravings and lithographs not executed within the United Kingdom, are unprotected by the Engraving Acts. The only exception to this rule exists in favour of works of that description under our International Copyright Acts, where such works have been *first published* in any foreign State with which Her Majesty has entered into a copyright convention. Thus, engravings and lithographs first published in France, Prussia, and several other States, may be protected here as to the copyright in them; but to acquire that protection, unfortunately, as the law now exists, a

double set of conditions must be performed: *first*, the name of the proprietor, and date of first publication in the foreign State must be engraved and printed exactly the same as if the print were first published in the United Kingdom; and, *secondly*, the print must be registered and a copy deposited at Stationers' Hall, London, *within three months* after the first publication of such print abroad. Unless all these conditions are performed, the copyright is utterly lost in the British dominions. We call attention to these facts, as they are of much consequence to the proprietors of foreign copyright engravings, whose property therein may with impunity be injured by the photographic or any other process of copying, unless the formalities we have pointed out are accurately performed.—*Athenæum*.

PHOTOGRAPHY IN TROPICAL CLIMATES.*

The difficulties in operating in a hot climate, after once getting on the right track, are not so great as some imagine. We were overwhelmed with difficulties, when we first attempted photography in India. In spite of everything we could try, likely and unlikely, the film would fog on developing. The only remedy we could find answer for a long time was to add considerable quantities of acid to the bath. This certainly got rid of fogging, but the length of exposure was enormously increased. At last it struck us that it was not so much the heat (as we have experimented in an artificially raised temperature), as the *energy and rapidity of chemical action* which goes on in the tropics, consequently if we reduced the number of particles to be acted on, or separated them further from each other, that we should thus neutralize their violent action. The thing was tried and found to answer very satisfactorily, the bath was reduced from thirty grains down to eight or ten grains to the ounce. This to many operators in England may seem incredible, they well knowing what effect such a course of procedure would have on the film here; but even then it was found necessary to allow but a very short time for immersion in the bath.

The strength of developing solutions was not of so much consequence, but even they were reduced with advantage.

Another difficulty to be encountered is the rapid drying of the surface of the film, giving use to fern-leaf markings. We tried, as we had found serviceable here, a pad of wet blotting paper at the back of the glass, but this was of no use. It then occurred to us, from the dryness of the shutter immediately in front of the glass, that it would possibly have a good effect to reverse the conditions. We then scraped the varnish or French polish off the inner side of the shutter, and kept it well moistened with water. This completely remedied that nuisance.

The dark room should be made in the coolest possible place near the glass room, not in it. The glass room should be situated in the shade of a tall house, if possible, to avoid every ray of sunshine. The sashes should be made moveable, so as to allow a good current of air. At certain times of the year, the sun is vertical at twelve o'clock; but the glass room can be so arranged as to be shaded without cutting off any of the effective working light. The only object in having a glass covering at all, is to screen off dust, wind, &c. A great portion of the year there is no rain worth speaking of, and when there is no wind, the sashes may be removed altogether.

One of the most general errors with regard to the construction of glass operating rooms, is that the more glass there is, the quicker will the picture be taken; nearly all glass houses are built of the preceding shape, which we will presently show to be a bad one, both for effect and shortness of exposure.

Light passes through a plane of glass with most chemical effect, when the line of its direction is at right angles to its surface. Such being the case, it is evident that a sitter placed at either end of a glass room constructed as above, can receive no direct light at all (as the light over his head *must* be stopped out, or it will give a person whose hair is black the appearance of having grey hair); all the light which comes to him must have been deflected from its original course, thereby losing a great deal of its chemical properties, besides which it will be found that, however far apart the sash bars are placed (consistent with the necessary strength), they will be found to intercept an immense portion of the light—not from the room, but from the sitter. There it is we want the light, the darker the rest of the room, the better for effect and comfort to the sitter. As the angle of the incidence and reflection of light are known to be the same, it follows as a natural consequence, that where a ray of light from the sky to the sitter has to pass through the glass at such an acute angle, a great portion of it never passes through at all, but is reflected off again. This may be very familiarly illustrated by observing the blaze of light which may be often observed coming from a cottage window (which may be seen for miles), when the sun is shining. This is light which has impinged on the window at too acute an angle to pass through it; for we must recollect that glass, though transparent, has a highly polished surface.

We have found the following shape of glass room, although not so complete-looking on its exterior as the preceding, a very great improvement both in its convenience and effectiveness. The tallest end for the background, B, is square—a great advantage in taking groups—while all the rest of the room not actually wanted for light may be built of any opaque material, to keep out the heat. The quantity of glass surface need bear very little proportion to the size of the room, as ten feet of glass from the sitter (or from A to C) is sufficient, no matter how long the room may be. If the room is sufficiently wide, there need be no side-lights at all. About three or four feet from the background of the under surface of glass, from A to B, may be blackened or built of opaque material, as shown in the drawing. Supposing the room to be twelve feet wide, the highest part of the roof, A, should be about ten, sloping down for about eight or ten feet from the sitter, or A, to the lowest part, C, which may be a flat roof, leaded or tiled, or other opaque material, and which need be no higher than convenient to walk under. The sloping part just over the head of the sitter, A, B, may be hinged as a flap, to be lifted up when the weather will admit, as the warm air ascends to this the highest part. This makes an admirable ventilator, even in this country, in summer. The back, B, should be placed against a tall house if possible, while the rest should be placed so as to have no obstructions.

The interior of the room should be coloured a *pale green* colour, without pattern of any kind, as a pattern would distract the eye of the sitter.

The blinds on the top-lights, E, may be made to pull down from A to C; spring-blinds are best, if good. The side-lights, D, may be managed with curtains.

* From "Practical Advice to Amateur Photographers," by Henry Matheson.

We will venture to say, that no one working in such a room as we have just described, and which is equally recommended as the best for efficiency here or abroad, would ever wish to alter it, after experiencing its comfort and rapidity as we have done. To such, however, as are in possession of a house such a house as we first described (as many are from unavoidable circumstances), it can be much improved by painting out all the light with the exception of the proportion shown in the last drawing.

A good plan to keep the collodion and chemicals cool, is to wrap a rag kept constantly wet round the stock bottles, and to keep them in the dark.

As water is not so conveniently laid on in the houses in India as here, it would be as well (as the water is generally brought in skins) to have a large earthen vessel or "chattie" placed on a firm bench higher than the head, and suspend a syphon with a tap and rag, to keep back the insects. This should be frequently cleaned out. The water will keep cooler in the earthen vessel than any other.

In out-door manipulation the operator will have many local difficulties to contend with; but if he keeps to the formulas here advised, he will find very little, if any, more difficulty than in this country.

The light, although the visual rays are very intense, has not so much chemical power on the film as one would imagine. Our idea is, that it is owing to its chemical properties being immediately absorbed by surrounding objects.

FOGGING NITRATE BATHS.*

Among the many difficulties encountered by photographers, probably there are none so general and annoying as "fogging nitrate baths," remedies for which have been proposed and published *ad infinitum*. With one, a certain remedy may prove applicable and satisfactory, while, with another, every effort to obviate the trouble results in vexation and disappointment; and, after repeated trials, the baffled experimenter concludes to send his bath to the chemist, and have the silver taken out. Precipitation in the form of a chloride, and reconversion to nitrate of silver, is unquestionably the most philosophical and certain cure. But in the hands of one who has had little experience in practical chemistry, this course involves great danger of failure and consequent loss.

When a bath becomes foggy, it is a sure indication that organic matter has been introduced into it in some way, and when this organic matter is removed, the silver solution is restored to its normal condition. A plan I have pursued to effect this object, which has in every instance proved entirely successful in point of time, economy, and thoroughness of cure, is the following:—

Evaporate the solution in a water bath, to the extent of one-half its bulk; allow it to cool, and then add as much freshly precipitated oxide of silver as it will take up (a slight excess will do no harm), supplying a small portion at a time, and shaping it up the while briskly; pour the solution into a clear glass bottle, and put it in a position where the sun may be on it until it is perfectly clear, and no further precipitation takes place. Upon first exposure to the sun, the solution will turn of a reddish brown colour, then black. The black sediment (precipitate) is organic matter with its equivalent of silver. To thoroughly accomplish this result may require two or three days' exposure. At any rate, *be sure there is no further precipitation*; then filter it carefully, and add to it about one drachm *kaolin* (china clay); shake it up, and let it stand over night. Now expose it to the sun, as before. Alkalinity may result from the presence of the oxide of silver. If, on testing, such should prove to be the case, remove it by adding one drop of C. P. nitric acid, and mixing it thoroughly with the solution. Now try a plate. Should the solution still show signs of alkalinity, add one drop more of nitric acid, try another setting, until the alkalinity is removed. In the addition of nitric acid, care must be exercised to avoid an

excess, as, in such case, the necessity arises of again adding *more cautiously* the acid.

The recommendation for the above course is its simplicity and certainty. There need be no failure in the adoption of it by the most inexperienced photographer, and certainly no waste.

The oxide of silver may be prepared by adding a solution of caustic potash to a solution of nitrate of silver, and washing the precipitate thoroughly with pure water. Aqua ammonia must not be used in lieu of caustic potash.

It must be borne in mind that the above is only applicable to a bath in which *no acetic acid* has been used. Acetic acid has no business in the bath—it belongs to the developer only.

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, May 13th, 1863.

DR. MONCKHOVEN describes a simple and easy method of analyzing silver baths. Take a glass tube, whose internal diameter is 1 centimetre, close it, and round one of its extremities in the flame of a spirit-lamp, and cut the other with a file, so as to leave a length of 50 centimetres, 20 inches. Weigh successively (1) 30, 60, 90, 120, 150, 180, 210, 240, 270, 300, and 330 grammes (of 15 grains each) of mercury, and introduce, after each weighing, into the tube. On the outside of the tube, mark the level of the liquid with a diamond or steel point; then pour the mercury into the scale, and proceed with the next weighing. After the last weighing, and the eleventh marking, cut the tube with a file just above this last mark; then, with the diamond, write O at the first mark, and successively 2, 4, 6, 8, 10, 12, 14, 16, 18, 20 at the succeeding marks; and, with a compass, subdivide these divisions, and also mark the odd figures comprised between 1 and 19.

On the other hand, take some clean culinary salt and put it into an earthen pot with a cover; place the vessel in a hot oven, or over the fire, and do not be alarmed at the noise made by the decipitating salt. When it is quite dry, weigh 6.9 grammes of it; weigh, also, a gramme of chromate of potassa, and dissolve it in an exact kilogramme of water, by weight, and not measured.

Distilled water, or, at least, rain water, is necessary for this purpose. After filtering, preserve the liquid for use in a well-corked bottle.

To make an analysis of any kind of silver bath employed in photography (even the aceto-nitrate bath), put some of it into the tube, up to the level of the first mark O. It is well to employ, for this purpose, a small glass funnel, with a fine pipe; for it is necessary to operate with great nicety. Pour in the salt liquid, small portions at a time, closing the tube each time with the thumb, and then shaking it. A moment arrives when the precipitate, first of a flesh colour, will become white. Read off, upon the exterior of the tube, the figure which corresponds to the liquid; this is the exact strength of the solution to be analyzed. A second experiment made, by employing very small quantities of the salt solution, especially when compared with the quantity marked by the preceding experiment, will give a more correct analysis.

M. Mc. A. Gaudin, commenting, in *La Lumière*, upon an article in the PHOTOGRAPHIC NEWS upon the new iron developer, says:—The principal advantage of the double salt of iron and ammonium consists in the stability of its composition, which is not influenced by contact with the atmosphere; while the ordinary protosulphate, even in crystals, offers quite a series of bodies more or less energetic. There is, first, the prosulphate, in blue crystals, which possesses the maximum of reducing power; and there is the ordinary sulphate of commerce in large crystals, of a brownish green, which contain a notable proportion of the protoxide salt. In my

opinion, this latter salt is the best, and the uncertain results must be attributed to the variability of the principal salt itself, which retains a definite composition with difficulty. From this fact, it is difficult to admit that the double salt procures a positive sensibility in comparison with the simple salt; but, on account of the constancy of its composition, it contributes better to a preparation possessing properties almost invariable, and permitting the avoidance of the accidental fogging peculiar to the sulphate of protoxide of iron under conditions which have not yet been defined.

Whichever sulphate of iron is employed, it is just the same; but its state in reference to the protosulphate type is unknown, and it is impossible to know the exact proportions of acid and of sulphate to employ, under the same conditions, as with another sulphate. But, in reality, the spontaneous oxydation of the protosulphate in contact with the atmosphere never diminishes its reducing power to the point of permitting its employment without the addition of acid.

SCHERING'S ENAMELLED PAPER.

SIR,—I mentioned a week or two ago in a letter, that I believed Mr. Schering's enamelled paper to contain a preparation of lead.

I have since been informed by that gentleman that such is not the case, and he has requested me to state this to you in the hope that you will give it the same publicity which you so kindly did to my former letter, as it might prove to the detriment of the sale of his paper, were the public to think that it was prepared with lead.

It appears that I was misled in my idea of his paper, owing to a sample which I once tried having turned grey in the fixing bath, but I now find that my failure was owing to my having toned the picture for too long a time.

May I request you to be kind enough to insert this communication in your next week's publication?—I remain, dear sir, faithfully yours.

N. JOCELYN.

Berlin, May 11, 1863.

Photographic Notes and Queries.

ANOTHER CAUSE OF FADING OF POSITIVE PRINTS REMOVED.

SIR,—I should propose that some very extra thick paper (about as substantial as the card used for mounting) might be made and albumenized in the usual way, when cut to the size required it might be printed upon no more than the exact size of the *carte de visite* (2½ by 3½ inches) by masking the margin all round of the respective picture on the negative: whereby much work, time, expense, &c., would be saved, besides the liability of the fading of the print by the more or less acid condition of the gum, paste, or other medium in mounting *cartes de visite*.

Should you think this of public interest you are quite welcome to it.—Yours respectfully,

P. T.

[We fear that the operation of printing on card or stout paper, together with the masking and necessity of preserving clean margins, &c., &c., would involve manipulatory difficulties which would outweigh the advantages to be gained; but the plan may be worth trying.—ED.]

Talk in the Studio.

AMATEUR PHOTOGRAPHIC ASSOCIATION.—A very handsomely bound album, containing a choice selection of photographs, by members of the Amateur Photographic Association, was presented to His Royal Highness the Prince of Wales, on Friday last, by Lord Caithness, accompanied by Mr. Melhuish, the Hon. Secretary of the Association. His Royal Highness was much pleased with the album and desired the secretary to express his gratification and pleasure to the council and members. A very large number of fine negatives have been, we are informed, sent in this year by members, many of which are from abroad, and include scenes in Egypt, India, Java, Canada, Italy, &c.

MR. VERNON HEATH'S EXHIBITION.—On Friday and Satur-

day last, Mr. Vernon Heath invited his friends to a private view of his latest landscape photographs, at his gallery, in Piccadilly. The pictures consisted of a new series of the castle and park, at Windsor; of additional views of, and around, the Grange, the seat of Lord Ashburton; of some charming pictures of Burnham Beeches, and the neighbourhood. All the pictures were characterised by the combined delicacy and brilliancy by which Mr. Heath's photographs have been distinguished, with the added charm now conferred by the presence of natural clouds and sky.

PHOTOGRAPHIC PIRACY OF ENGRAVINGS.—*Court of Common Pleas, Westminster, May 8.* (*Sittings in Banco, Easter Term, before the Lord Chief Justice ERLE and Justices WILLES, BYLES, and KEATING.*) GAMBART V. MAYNE.—This was an action for the infringement of the copyright in the "Light of the World" by the defendant, a bookseller at Exeter, for selling a photograph of that engraving to the plaintiff's attorney's son. The defendant set up the defence that he had denied having any copies to sell when asked, but that his daughter, who was present, said she had had a small copy given to her, which she offered to give the plaintiff's attorney's son, who, however, insisted upon paying for it, and the defendant's daughter then said if he paid for it she would have the money, and a person in the shop said, "Well done, young lady, I am glad you insist on your rights." The jury, therefore, found a verdict for the defendant. Mr. Brandt now moved for a new trial, on the affidavit of a person in Exeter that he had seen photographs of the print in the defendant's shop window, and that the defendant had himself shown him copies and offered to sell one to him, and had boasted of selling them. The court said the application was too late. The witness might have been called at the trial.—*Rule refused.*—*Times.*

AID TO TONING.—Mr. H. Cooper sends us the subjoined:—The following suggestion may, I hope, be of some use to your readers. During the preliminary washing of photographic prints, dab the surface with a clean sponge, before toning. This will effectually remove any deposit of chlorides, &c., from them, and materially conduce to even toning. If, whilst toning, any deposit falls, it can be removed in the same way. When prints are left to *soak* in water, they should be face downwards.

ENGLISH PHOTOGRAPHY IN FRANCE.—The Paris correspondent of the *Daily Telegraph*, speaking of the present Academy Exhibition, remarks that English photography takes the highest position there. He says:—Adjoining the picture gallery is a vast and splendid display of photography, of which, as the catalogue is not yet printed, I cannot speak with certainty either as to performances or artists; but I am sufficiently a judge, and my opinion was confirmed by native and foreign artists, to say that England bears off the palm. Mr. Robinson's picture, "Bringing Home the May," was greatly admired as an elaborate and highly-finished work. The "Views in the Pyrenees," photographed for the Emperor by Mr. Maxwell Lyte—who, with a classical and original if simple wit, writes "*Lux fecit*" at the bottom of his pictures—are very true to nature and very beautiful, but they and all the other photographs want what is so striking in the "Views near Naples," sent over by Colonel Stuart Wortley. This gentleman seems especially to have studied the effects of atmosphere and of water, and in his pictures, instead of the hard straight line which in photography defines the boundary between the view itself and the blank white which stands for sky and water, you have the varied light and shade of the passing clouds and the changing face of the rippling sea. The former is especially to be perceived in the "Sunrise during the Eruption of Vesuvius;" the latter effect is wonderfully produced in the "Wave rolling in," which is the gem of the Photographic Exhibition.

RAPID TANNIN PLATES.—A correspondent in Berlin writes as follows:—"I have been trying with considerable success the rapid tannin process, developing with ammonia. There is with me always a slight veil, at least, with Ponting's collodion, but this I can altogether get rid of by using a collodion containing a good deal of free iodine, but at the expense of rapidity. I should like much to know Mr. Hurst's method." Our correspondent should try the addition of bromide to the collodion in question. We hope shortly to have Mr. Hurst's permission to publish his method.

MOUNTING PHOTOGRAPHS.—A correspondent says,—"Perhaps the following will be of use to some of your correspondents, as I think it is generally considered that glue is the best substance for mounting prints, but not much used by amateurs on account of the trouble of preparing it every time it is required to mount

a few prints. If a small quantity previously melted be poured into a bottle and allowed to cool it may be got ready for use in two or three minutes by standing the bottle in hot water."

PHOTOGRAPHY FOR TOURISTS.—A new work on "Dry Collodion Processes," written with an especial view to the wants of tourists and of missionaries and scientific travellers, by Dr. Kemp, of Cambridge, is announced as in the press, and shortly to be published.

To Correspondents.

TYRO TANNIN.—Our own experiments with the recent variations of the tannin process have not been extensive. For the purpose of obtaining the best information, we have submitted your queries to Major Russell, and hope to be able to give you his answer in our next.

F. VINCENT.—The collodion to which you refer has many excellent qualities; but unfortunately some samples give the mottled reticulated effect which you describe. Reducing its thickness by the addition of equal parts of ether and alcohol will decrease the tendency, but we fear nothing will entirely remove it when present.

A. POOL AMATEUR.—We believe that pitch alone is used for attaching lenses to the holder in grinding. 2. Blotting-paper as a lining for your plate-box will be quite harmless. 3. There is no work treating especially of photographic lenses, nor any work on optics giving much attention to the subject. The only published information on the subject is scattered about, and is for the most part meagre, and often unsatisfactory and untrustworthy. There is no periodical called "The Optician." 4. A quarter-plate portrait combination for 13s. 6d. cannot, in the nature of things, be very good. It is quite possible that the lens No. 1 in the catalogue you name may answer your purpose, but you must remember that no ordinary quarter-plate lens is well calculated for taking card portraits of standing figures. To be well suited to the work in question a special construction is required for lenses of such short focus. For sitting figures they may answer, if good, very well, and for standing figures by using a very small aperture, which of course increases the time of exposure. We have every reason to believe the dealer you name to be a respectable man. But bear in mind in reference to lenses, as to everything else in the world, "the worth of a thing is just what it will bring." A first-class article will always command a good price, a moderate article a moderate price, and a bad one a bad price. The authority whose words you quote in favour of cheapness is a very insufficient authority on the subject of lenses, and his words were disproved by the illustrations brought forward at the time. The thorough testing of a lens is not a task which can be successfully undertaken by an entire novice. Your best plan will be to write to the dealer, as you propose, telling him the circumstances and asking him to select you one.

R. T.—So far as we can see from your specimen your lenses are placed in the right position in the camera, but the partition in the camera does not come sufficiently up to the ground-glass to prevent one image impinging on the other, and so causing the blurred space between them. When the lenses have no lateral movement, the usual distance between the lenses is 34 inches, so that the centre of each image may fall on the centre of each half of a 63-inch plate.

G. A. B.—The small, irregular, white patches which you describe are doubtless reduced silver, and may proceed from several causes. The most common are contact with some reducing agent on the frame in the dark slide, insufficient acid in the bath, or the presence of organic matter, too long a time between exciting and developing; this latter may be the case without actual drying of the film in the place. 2. We are very familiar with the brown or red deposit on the shadows which you describe, you will find it fully treated on page 361 of our fifth volume, and on page 45 of our present YEAR-BOOK. The plentiful use of citric acid, or, better still, a wash of iodine solution previous to intensifying will prevent its occurrence. 3. B, probably of the makers you name. 4. We use plates 7½ by 5, and 5½ by 3½. 5. The washed collodion process as described by Mr. Hislop gives the best results we have seen.

ALPHA.—A little more intensity in your negative would make the print not quite so heavy, or a little less printing with the present negative might be better. But the picture is by no means bad. We cannot tell you of any simple or easy mode of ascertaining whether engravings are copyright, but as a general principle you may presume that all published within the last twenty-eight years are so.

A. BEGINNER.—The printing and tone of your print are not at all bad—the hardness is in the negative. In the toning formula you mention, the proportion of carbonate of soda is not so large as to be dangerous, but the acetate bath is better. If you get better and softer negatives, and print as well as hitherto, the results will be good. The price of our ALMANAC is one shilling. The lens to which you refer will answer for a beginner.

D. DUNNAN.—We are not aware whether any of Liesegang's enamelled paper is to be had yet in this country. Your results with Schering's are very good. What method do you use?

SPOTTY PRINTS.—The defect in the prints enclosed is meanness. The best remedy we know is slow toning, and the use of toning solution a few days old. A variety of remedies have appeared in our pages, but it sometimes happens with some samples of Rive paper, that all fail.

A. LUNATIC.—The Rive paper, highly albumenized, is sometimes very liable to blisters, especially when the toning and fixing solutions are decidedly alkaline. In order to get black and white tones you must use intense negatives, and print deeply. Any toning process will then give you black tones. The only means of preventing the prints becoming too much bleached in the fixing solution, is deep printing and toning, so as to allow for the inevitable bleaching.

M. D.—Your nitrate bath is surcharged with iodo-nitrate of silver. Dilute it with an equal bath of water, which will cause a precipitate; filter, and add sufficient silver to make up the proper strength.

M. AMBO.—With some samples of paper it is impossible to prevent very considerable reddening in the hypo bath, and in such case a change of paper is the only remedy. But it sometimes happens that when the toning is

conducted very rapidly a deceptive black colour is obtained which rapidly disappears in the fixing bath. Use the acetate bath, tone a little deeper, and, if necessary, change the paper.

PYAO.—The stains on your pictures appear to arise from the developing solution running back from the edges of the plate in greasy streaks. The camera used cannot have any influence in the matter so as we can see, unless the plate rests on an edge all round, instead of at the corners only, which might affect the matter. You had better practise a little longer before seeking an engagement as operator.

W. H. H.—The black deposit thrown down is metallic gold. We have never had such a deposit with the acetate bath; try using less of the acetate, or another sample.

T. A.—We presume Mr. Glaisher's opinion as the nature of light is that universally held at the present day, known as the Undulatory Theory, and of which the Astronomer Royal, in his tract on the subject, says it is "certainly true," and possesses "the same claims to attention as the 'Theory of Gravitation.'" This theory supposes that the sun, as a luminous body, communicates an undulatory motion to an elastic ether which pervades space, and that the different coloured rays are due to the length of the waves or undulations; the red ray having the longest waves and the smallest number in a given space of time; and the blue ray the shortest waves and greatest number in a given space of time. As this is a well proved theory, confirmed by its explaining a number of incidental phenomena, and is universally accepted, we have no doubt that it is the view held by Mr. Glaisher. Should this not be the case, we have no doubt that he will inform you, on application. You must bear in mind that a subject which has been carefully investigated by the ablest men of the day, with the best possible facilities for its examination will not be lightly set aside. We cannot of course offer any opinion upon your ideas as briefly indicated in your note.

L. L. L.—The simplest mode of giving a dead black surface to paper is to brush it with a mixture of lamp-black and size. For rapid drying, a mixture of lamp-black with very little white lead, and turpentine will answer. 2. Wherever the word "part" is used it may mean grains, drachms, ounces, or any other quantities at the choice of the operator. It is the simplest possible manner of stating a formula, adapting itself to the commonest intelligence. Thus, the formula you quote, "100 parts of sulphate of iron in 500 parts of water" may be 100 grains, or drachms, or ounces, in 500 grains or drachms or ounces of water; if grains be selected the proportion will be at the rate of one in five, or, say 12 grains in a drachm of water. The only thing to be remembered is to use the same "part" throughout, by weight in solids, and measure in liquids, unless "parts by weight" are specially stated, in which case you must weigh. Where the term per cent. is used it is equally simple: a solution of 5 per cent. contains 5 grains to the ounce of water. Thus a silver bath of 5 per cent. contains 24 grains to the ounce, being 5 multiplied by 4 8/10ths. Where French formulæ are stated according to their decimal system of weights and measures, it is difficult to state them exactly in English figures without troublesome fractions, but where stated in "parts" and "per centages" the matter is very simple, and need merely requires the exercise of a little intelligence to understand them.

R. T. L.—Judging from the print received you have too little direct light and too much diffused light; but the negative appears to have been much over-exposed and under-intensified. So far as you state, your chemical conditions are all right, but the print is very poor, and it seems difficult to say with certainty the source of the error. Try with a much larger stop, and short exposure. If you send us a further example state exact time of exposure.

SOA.—Hollingsworth's paper may be used with resin; but the Rive paper gives the best results for the purpose. You may purchase the solution ready prepared, or you can get the materials, as described in our pages, of any chemist. It is quite possible to get pure whites with resinized paper.

W. D.—The value of negatives, and the facility of disposing of them, will depend entirely upon the subjects. If the subjects are popular, the negatives, or prints, from them will, doubtless, sell.

F. L.—We only know three causes for the defects of which you complain, viz., dirty plates, a bath too acid, or defective collodion. There are other minor causes which will tend to the same defect, but these are the chief causes. When the tendency exists, short exposure and over-pushing of development will increase the tendency. We fear, in this case, the collodion is the cause. No. 174 containing index to Vol. v. is, unfortunately, out of print.

T. G. sends a piece of glass flashed with silver, and having the peculiar mottled appearance characteristic of the best actinic qualities, has been sent for spectroscopic examination. It is seen to cut off in a very perfect manner all the chemically acting rays, and will answer very well for glazing the windows of a dark room.

CONSTANT SUBSCRIBER.—For camera printing of transparencies, the lenses should be placed upon a sliding front, so as to admit of a lateral motion, separating them more or less, as needed. This plan has many advantages, and permits a slight enlargement or reduction of the copy, which is often desirable. The distance between the two images on the transparency should be about 23 inches from centre to centre. You may use the lenses to which you refer, for producing the transparencies.

F. G. WHAITE.—We handed the five shillings to Dr. Diamond, for your share in Meagher's camera.

INCREASING OR REDUCING INTENSITY OF VARNISHED NEGATIVES.

WHEN a negative is varnished, its defects, if it have any, are generally considered as past remedy. It frequently happens, however, especially to amateurs, that the real printing value of the negative is not certainly ascertained until after it has been varnished and proved; it may then turn out that the deposit, which looked so comparatively thin, is so non-actinic that it prints hard; or, that notwithstanding an apparently dense deposit on the high lights, either from this density being factitious and permeable, or from the presence of too much deposit on the shadows, the prints are tame, flat, and wanting in contrast. It sometimes happens, moreover, that the negative, which really possesses a true relation of contrast in light and shadow before it is varnished, becomes, through some peculiarity in the film, so permeated and saturated with the varnish, that the opaque spots of high light become more than semi-transparent. All negatives are more or less reduced in intensity by the varnish, but in some instances the varnish appears to remain entirely on the surface, simply acting as a transparent protective film, affecting the printing character of the negative in a very minor degree; whilst in others, where the deposit is powdery and permeable, the intensity is considerably reduced. Thus, from a variety of causes, especially in the hands of the inexperienced, a remedy for such defects, a means of altering the intensity of the varnished negative, becomes a valuable power.

Various modes have been tried to remedy defects of intensity in varnished negatives. If what are termed "crystal" or "amber" varnishes have been used, the solvents of which are chloroform or benzole, the varnish is comparatively easily removed by repeatedly flooding the varnished surface with one or the other, especially with the chloroform; but with spirit varnishes, which are most commonly used for negatives, the case is different. The varnish once set is not easily entirely dissolved again, and even after long digesting with strong alcohol, and repeated washings with the same, a white powdery deposit remains, which seems so incorporated with the collodion film, that it is impossible to remove it. The remedy we are about to describe especially refers to negatives varnished in this manner, with any of the alcoholic or spirit varnishes in the market. Proceed as follows:

For a thin Negative.—Cover the varnished film with absolute or strong alcohol—methylated spirit will of course serve—so as to slightly soften and render permeable the varnish. Then take a weak solution of iodine, in alcohol, from four to six grains to the ounce, and pour over the plate. If the negative be thin and poor, giving prints lacking contrast, let this solution only remain on the film a few minutes, watching its operation carefully. An increased density is the result of the application, and a change of the colour of the deposit. The dense parts which in a weak negative are generally of a grey colour, become of a deep olive tint, which is very non-actinic. The film is then to be washed

quickly again with alcohol, and dried by gentle heat. It may be again varnished, but this it rarely needs, for in truth scarcely any trace of the varnish already there has been removed by the operation. We have produced by this means negatives giving brilliant prints, which before were so thin and flat as to be entirely worthless.

For an Over-Intense Negative.—Proceed in the manner just described; but instead of pouring off the iodine solution as soon as the non-actinic olive tint appears, continue its application, the colour of the deposit will become gradually a deep yellow, then of a primrose, and finally white. It may be stopped at any of these stages, just as the character of the negative and the density of the existing deposit may require. It is evident that whilst a dense deposit of a black or non-actinic colour may give very hard unsatisfactory prints, the same kind of a deposit when changed to a colour more permeable by light may give soft round good prints. The exact stage, then, to which the colour must be carried will depend on the amount of density present and the result desired; a little judgment must therefore be used. The film must then be washed with alcohol, as before described, dried before the fire, and in this instance varnished, as the prolonged treatment with a strong spirit will have removed a considerable portion of the varnish at first on the film.*

The same method both for increasing or reducing intensity, may be followed, using an alcoholic solution of bichloride of mercury, instead of iodine. The first application in this instance increases the density of the deposit and makes it of a bluish-black colour, not so non-actinic, however, as the olive tint produced by iodine. The prolonged action of the bichloride is similar to that of iodine finally turning the dark deposit light coloured, and reducing its printing intensity. The use of the mercury has, however, some objections which the iodine is free from, and we recommend the latter.

The method we have described especially refers to negatives produced by a deposit of silver only; but it is not less applicable to those which have been intensified by mercury and an iodide, or by other means; the principle of its operation being the same, some slight modification in the exact treatment being in some instances rendered desirable by the especial features of the case, which must be suggested by the judgment of the operator.

We may remark in conclusion, that, according to the old adage, they who are good at excuses are seldom good at anything else. In like manner they who are good at expedients are rarely skilful in dispensing with them, and whilst we furnish expedients for emergencies, we strongly counsel young photographers to avoid the necessity for them; to acquire as far as possible a certain and exact mode

* In a paper read by Mr. Berry some nine years ago before the British Association, he suggests that when a film is so tender as not to permit intensifying with aqueous solutions without being disrupted, it may be varnished and then intensified with alcoholic solutions of chloride of gold and sulphide of ammonium applied in succession, but we cannot recommend the plan, which, for various causes, never came much into use.

of operating, which places little reliance upon, and has little need for, after "dodging" of any kind. William Cobbett, in advising the young literary student to acquire a certain and exact habit of writing, recommends him never to erase or alter a word, but to compel himself to send forth his matter as first written, with all its imperfections, so that the mortifications he must suffer, for awkward blunders, may so conduce to caution that he will gradually acquire a habit of precision and exactitude which requires no correction. We do not exactly give this counsel to young photographers; we recommend them rather to destroy with ruthless hand their first crudities. But we do recommend them to acquire habits of certain manipulation, and to remember that in placing in their hands expedients of any kind, they are to be regarded as reserve power to be used in emergency, and not as encouragements to carelessness in one operation because the result can be modified in another.

THE ENAMELLED PHOTOGRAPHIC PAPERS.

We have already stated that some of the enamelled papers are prepared with oxide of zinc. We are now in a position to state that our original conjecture as to the nature of the enamel in some other specimens is correct. A sample we placed in the hands of an eminent analytical chemist proves to be prepared with sulphate of baryta in combination with albumen. The material used is probably the ordinary mineral white (powdered heavy spar, or native Ba O SO_4), which is in this country largely employed in adulterating white lead. Mr. Cooper's experience that it is insoluble in dilute mineral acids would be quite consistent with this material. We see no reason to apprehend any injurious influence from it, either to the silvered bath or to the finished photograph.

PHOTOGRAPHIC CHEMICALS.

THEIR MANUFACTURE, ADULTERATION, AND ANALYSIS.

DISMISSING silicic acid for the present, we will pass over a series of metals which are either too rare or not sufficiently important, to require treatment in these chapters.

The next body which claims attention from the importance of many of its compounds to the photographer, is chromium.

This metal forms two or three oxides of interest to the photographer, the brown oxide, sesquioxide, and chromic acid. We will, in this case, reverse our usual order in describing metallic compounds, and treat of the acid first, as it is this body, in combination with potash, which is mostly used for photographic purposes, the lower oxides being generally the result of the action of light. Chromic acid forms carmine-coloured needle-shaped crystals, rapidly deliquescing in the air, and dissolving very easily in water, forming a dark reddish brown, or lemon yellow solution. The concentrated acid corrodes paper like oil of vitriol, and when in dilute solution, it likewise attacks paper and other kinds of organic matter, especially when aided by light or heat, becoming converted into the brown oxide or the green sesquioxide, according to the extent of the decomposition. Chromic acid is too energetic and unmanageable an agent to be used in the pure state for photographic purposes. It can, however, be converted into an acid salt with potash, in which form it possesses very valuable properties. Bichromate of potash is the name given to this compound. It is composed of one part of potash and two parts of chromic acid. In most places, bichromate of potash can be purchased ready made, and then nothing more is necessary than purification, before it can be employed for photographic purposes. It may, however, sometimes happen that bichromate of potash may be wanted when only the materials for making it can be obtained, and as its preparation is not difficult when the ordinary resources of a laboratory are available, we shall now give the most approved method of manufacturing this salt direct from the ores. Chrome iron ore (a mixture of

sesquioxide of chromium with protoxide of iron) is finely powdered and ignited with an equal weight of nitre. The mass is raised to a bright red heat in an earthen or iron crucible, and kept at that temperature for a considerable time. It is then boiled out in water and filtered from the insoluble portion. The aqueous solution contains chromate, silicate, and albuminate of potash, together with nitrate and nitrate of potash. To this add nitric acid, until the alkali in the liquid is exactly neutralized, the acid being added in small portions at a time, until the lemon yellow colour of the liquid begins to change to reddish yellow. The alumina and silica will be by this treatment precipitated and can be filtered off. Evaporate the solution to the crystallizing point, and separate the resulting yellow crystals of chromate of potash. This salt is liable to contain as impurities, silica, alumina, chlorine, and sulphuric acid. From the first two it is separated by repeated crystallization, and the sulphuric acid is removed by adding a little nitric acid and adding nitrate of baryta until there is no further precipitation of sulphuric acid. To the filtrate nitrate of silver is added as long as chloride of silver is formed; after which the solution is filtered, evaporated to dryness, and the residue ignited in a platinum crucible. The residue is dissolved in water, and the solution left to crystallize. Yellow chromate of potash has an alkaline reaction and a cooling persistently bitter and metallic taste; it is permanent in the air, it is tolerably soluble in water, dissolving in twice its weight at the common temperature, and in about $1\frac{1}{2}$ times its weight of boiling water. It is insoluble in alcohol. It possesses remarkable colouring properties: one part of the salt imparting a distinct yellow colour to 40,000 parts of water.

The mono-chromate of potash is very little used in photography in comparison to the bichromate; it is, however, the salt from which the latter compound is always prepared. Take a saturated solution of yellow chromate of potash, add nitric acid to it, and evaporate the liquid at a gentle heat to half its volume: bichromate of potash crystallizes out on cooling, together with nitre. The two classes of crystals are so dissimilar to one another that there will be no difficulty in separating the two salts by mechanical means. The bichromate forms bright-red rectangular, four-sided prisms, whilst the nitre occurs in smaller colourless crystals. The red salt must be redissolved in water and purified again by crystallization. It crystallizes very readily in large prisms which have a cooling, bitter, and metallic taste, redden litmus, and are permanent in the air. When three parts of this salt are heated with four parts of oil of vitriol oxygen gas is evolved. According to Balmain, this method gives perfectly pure oxygen, and at a cheaper rate than when chlorate of potash is used.

The great use of bichromate of potash in photographic operations is due to the ready way in which it parts with some of its oxygen to organic matter under the influence of light. Bichromate of potash may be looked upon as containing one part of chromic acid in the free state. Now chromic acid has a large quantity of oxygen locked up in it (three equivalents of oxygen to one equivalent of chromium) and it is somewhat of an unstable compound, having a tendency to give up oxygen and pass to a lower state of oxidation at the slightest opportunity. When placed in contact with an organic substance, such as paper, gelatine, leather, horn, parchment, the skin, &c., the oxygen of the chromic acid is ready to unite with the carbon and hydrogen in these bodies. The change goes on, however, very slowly in the dark, requiring the stimulating action of light to set it up, but under this influence it speedily passes to the state of brown oxide Cr O_2 , and then to the sesquioxide $\text{Cr}_2 \text{O}_3$.

By some chemists the brown oxide is looked up as a compound of chromic acid with sesquioxide of chromium. This appears a very reasonable view of the question. Chromic acid forms salts by union with most, if not all, bases; and on the other hand chromic oxide (sesquioxide of chromium) forms salts by union with most acids. Why, therefore, should not chromic acid form a salt by union with chromic

oxide? In fact this is what takes place when neutral chromate of potash is added to a neutral salt of sesquioxide of chromium, a chromate of chromium is precipitated in the form of a yellowish brown powder. According to this view then the brown binoxide of chromium Cr_2O_3 would be represented by the formula Cr_2O_3 , Cr_2O_3 which equals Cr_3O_6 or three times Cr_2O_3 .

This, then, the formation of brown chromate of oxide of chromium, is the first result of the action of light upon a mixture of bichromate of potash and organic matter, and occasions the brown tint left behind in the paper when the chromate of potash and the carbonate of potash (the carbonic acid being derived from the oxidation of the carbon of the paper) is washed out. If the action of light is allowed to proceed further, the deoxidation ultimately proceeds to the greatest possible extent, and the chromic acid is entirely reduced to the state of sesquioxide of chromium. This has a green colour, and its presence may often be observed in photographs printed in this manner. The reduced brown oxide of chromium, just mentioned as having the properties of a salt, reacts in several ways, like a combination of an acid and a base, and when washed with various metallic and other solutions, gives rise to other insoluble metallic compounds of various colours, by a process of double decomposition. Hence the numerous bichromate of potash printing processes in which variously coloured positives are produced. So far, then, for the action of bichromate of potash upon paper under the influence of light.

Upon gelatine, in its numerous forms of gelatine, isinglass, glue, and the allied bodies, gum, &c, another action takes place at the same time. The reduction of the chromic acid is effected in the same manner, but the oxygen which it loses attacks the gelatine and converts it into a slightly different chemical substance, rendering it partially or entirely insoluble in water, and unacted on by that menstruum.

DOUBLE OR FANCY PRINTING.*

BY R. HARMER.

In complying with the request of your Committee, to describe the method I adopt in double or fancy printing, I will endeavour to be as practical as possible in what I have to say. The proofs in illustration I have purposely taken from the same negative.

The first I would call your attention to is printed as the negative gives it—such a print as I should receive were I to send out the plate and order a dozen to be printed. You will see that it has an amateur background of brown paper, rough and inartistic. It was taken out of doors. This being altogether unsatisfactory, we proceed to make a vignette of it, for which purpose I prefer placing in front of the glass a piece of brown paper, with an aperture filled in round the edges with wool, considering that a much more artistic vignette is produced in this way than by using the vignette glass, which merely gives a shaded oval. With the paper vignette you can, during the printing, enlarge the aperture and vary the effect.

While making these remarks I must beg of you to imagine that a vignette proof has been printed, which I now remove from the frame, and in place of it put a mask of black paper and again place the print in a frame. The parts required to be kept from the action of light are covered by a small piece of wool, which may be made to adhere to the glass by slightly damping as far as the outline of the figure. The wool should then be pulled out to a thin film, to ensure softening into the tinted ground about to be produced. The frame is now ready to be exposed again to the light, which should be done in the shade, as it gives greater control over the tint, and the necessary softening of it into the vignette. Two or three minutes (keeping it moving all the

time) will generally be found sufficient to produce the depth of tint required.

The proof now shown will be the result. Other shapes for the masks will suggest themselves, this being entirely dependent on the taste of the printer. Should fancy lead you still further, it may be done by preparing an ornamental design, bearing in mind that what is black in the design will be white in the finished proof. The ornamental mask thus prepared, nothing remains but to use it in the same manner as the mask of black paper before described. Practice will alone tell the depth necessary to print. One tint and one shape will, as a rule, give the best results; the danger to avoid is over-doing it.

I do not think that this style of printing will be of much value commercially, on account of the care and attention required; but to amateurs whose negatives, for want of the necessary appliances, are imperfect, and who desire to make the best of them, I would recommend them to give it a trial, feeling assured they will find an opportunity for the display of artistic taste, and, at the same time, save many of their negatives being cast aside as worthless.

For the information of some who have been making inquiries as to when I first made use of this style of printing, it was when photography was styled photogenic printing. Leaves, lace, and feathers, being about the only objects copied, my first vignette was a leaf, and when printed, a perforated card, with a lace border, was laid over it, and again exposed to light, which I presume may be called double printing. This must have been about twenty-five years since, so that there is nothing new in it; it is merely revised with improvements, and very possibly others may have done the same thing.

It is a frequent occurrence, both in science and art, for two individuals to be working out similar ideas. I was struck with this on reading in last week's PHOTOGRAPHIC NEWS a letter from America by Mr. Thompson, in which he states that Mr. Moran, of Philadelphia, had made some moonlight pictures by double printing; singular to say, some months back I prepared the cloud sketches now shown for the same purpose, but have made no use of them for want of a suitable negative—a negative which prints hard, giving a white sky, would be suitable for the purpose, and no doubt some fine effects may be produced.

In conclusion, I have to thank you for your attention; and if I have omitted describing anything with sufficient clearness, I shall be pleased to answer any inquiries.

RESEARCHES ON POSITIVE PAPER.

BY DR. SCHNAUSS.

I PUBLISHED, in the *Moniteur de la Photographie*, during the year 1862, an article, "On the Effects of Affinity in Photography," and among other operations, I spoke of gold toning. I endeavoured to show that the photographic proof, or a piece of paper prepared photographically, exposed to the light for a certain time, contains on its surface silver in the metallic state, that is to say, perfectly reduced. Similar researches, I know, have been frequently made, but not from the point of view I take in seeking to establish that in toning, by means of the alkaline gold toning bath, not only is the gold deposited upon the paper, but that also an equivalent quantity of silver is converted into chloride of silver, in the same manner as when a metal is separated from its solution by another metal which is more strongly electro-positive. It is only pure metallic silver that can accomplish this, and not sub-chloride of silver. My researches were not then sufficiently complete, because they formed only a part of a more important work, intended to establish the effect of affinity in photography in general. Nevertheless, this part has attracted much attention and contradiction. For this reason I have been induced to repeat and complete my researches. MM. Girard and Spiller, especially, have thrown doubts on my assertion that

* Read at a meeting of the South London Photographic Society, May 14, 1863.

photographic papers, exposed for a long time to the light, toned with gold and fixed, contain only gold. My researches persuade me that it is a certain fact, and I have found that it is not impossible to establish the presence of minimum quantities of silver in the ashes of the photographic paper, even if they contain much gold.

I have examined the ashes of photographic papers which were treated with a weak solution of chloride of gold—the one *before* and the other *after* fixing; and also papers treated with a bath of *sel d'or*. The papers were well washed, the toning and fixing continued not less than half an hour, and sometimes an hour. After fixing, the papers were treated with a weak solution of ammonia.

The papers, having been prepared upon a dilute solution of chloride of ammonium, dried, and sensitized upon a solution of nitrate of silver (1 : 9), the paper was next day exposed to the light. I also, sometimes, employed paper prepared with arrowroot, without finding any perceptible difference. Of course, these experiments cannot be made with papers, the coatings of which combine chemically with the nitrate of silver, as albumenized paper for example. The paper, moreover, must be employed only quite fresh, because the silver combines with the fibre if the paper be sensitized some time in advance.

In my first essay I endeavoured to prove what I had said the previous year, that paper sensitized and exposed to light, if it remains very long in a dilute gold bath, loses almost entirely its metallic silver, and contains gold only—that the silver is formally replaced by the gold. The paper prepared as described above,—of the size of a normal plate—was exposed to light until its surface was completely bronzed. I afterwards carefully washed it, and cut it in two. I put one-half in a dilute solution of chloride of gold (1 : 2000). After leaving it in the solution for an hour, it was well washed, and fixed in a fresh solution of hyposulphite of soda, it was again washed in dilute ammonia, and, lastly, in plenty of distilled water. This paper, viewed by transmitted light, was quite clear, and of a fine violet-blue colour: its surface had a very fine velvety appearance. It is easy to perceive the silver in a toned and fixed proof, by viewing it by transmitted light. The silver is brown, the gold is blue.

The other portion of the paper was immediately fixed in hyposulphite of soda, and washed.

M. Professor Reichard, of the University of Jena, a chemist well known by his excellent analytical works, had the kindness to examine the two portions of paper. Each piece was burned in the flame of a spirit-lamp, and the ashes were boiled in a platinum crucible with nitric acid.

The nitric solution of the ashes diluted with a little water gave no remarkable turbidity with hydrochloric acid. After dissolving the residue of gold in *aqua regia* a slight black residue remained: chloride of silver could not be extracted from it by treating it with ammonia. The solution of gold was quite clear. Thus it was proved that there was no remarkable trace of silver in this paper toned with gold. The nitric solution of the ashes of the other half of the same paper which had not been toned with gold, gave a strong precipitate of chloride of silver with hydrochloric acid. Where then was the silver in the first portion of paper, if we suppose with some chemists that the gold is precipitated upon the silver without the latter being changed?

This experiment with the paper toned with gold was repeated three times. Once only was the nitric solution of the ashes made a little turbid upon the addition of hydrochloric acid. But even if it were possible to find traces of silver in small quantities it would not be in proportion with the quantity of metal contained in the proof not toned; consequently the metallic silver is changed in the gold bath into chloride of silver. The following experiment proved that view. A sheet of paper prepared and exposed to light, as before, was fixed and afterwards toned. It assumed the same blue tone as the paper toned before fixing, but it contained much silver, or rather chloride of silver. This is per-

haps one reason why proofs toned after fixing have a colour so little agreeable to the sight, that this method has long since been abandoned.

Now I have never pretended to assert that photography can, with every known gold bath, change its silver proofs into gold proofs, but only sought to discover if the silver reduced upon the paper acts upon the solution of pure chloride of gold in the same manner as metallic silver, and if this latter metal separates itself by its greater affinity for chlorine; I have also examined a bath of *sel d'or* from this point of view, and I have found that in this case the change, that is to say, the substitution of the silver by gold is made only partially.

In the course of my researches I have found that it is not difficult to prove the presence of minimum quantities of silver along with large quantities of gold, because in this case they are not alloys, but only mechanical mixtures of gold and silver in a state of fine division. Every trace of silver which has not been dissolved by nitric acid shows itself during the solution of the gold in *aqua regia*; it may be extracted from the black washed residues by the aid of ammonia, and precipitated by hydrochloric acid. As concentrated *aqua regia*, especially if it be heated, dissolves a little chloride of silver, the mixture of acids must be slightly diluted.—*Le Moniteur de la Photographie*.

COPYRIGHT IN PHOTOGRAPHS.

REPORT OF A COMMITTEE APPOINTED BY THE EDINBURGH PHOTOGRAPHIC SOCIETY.

A COMMITTEE was recently appointed by the Edinburgh Photographic Society to report upon the provisions and construction of the new Copyright Act, in relation to photography. In order to raise the points of most importance, a special meeting of practical photographers was called, who were asked to submit such questions as might appear desirable. The report is framed as answers to the questions. We reproduce the principal portion of the report from the *British Journal*, with the exception of a portion of it which was extracted from the PHOTOGRAPHIC NEWS ALMANAC. We also append one or two comments, in passing, on the report, which appear to us to be necessary.

QUERY I.

Whose is the Property of the Negative of a Photograph made for any one without Special Agreement as to the Proprietorship of the Negative?

The contract, in the case supposed, is for the execution merely of so many completed photographic copies of the work ordered, and the photographer in executing the order requires to produce a negative, about which no special agreement has been made.

The Committee think it clear that the negative does not belong to the customer, without special agreement to that effect. It must remain in the possession of the photographer. But his right will be only a limited or qualified right of property, and he cannot use the negative for any purpose, or in any way other than his customer may permit; for such use of the negative would be a violation of an implied contract with his client, that the work ordered should be produced for him alone, and for his purposes only.

QUERY II.

Is Registration Necessary to give the Copyright to the Person Ordering the Negative?

By the first section of the statute the person ordering the painting, drawing, or photograph, is entitled to the copyright thereof, provided they shall be made or executed for a good or valuable consideration. And by the fourth section it is enacted that no proprietor of any copyright shall be entitled to the benefit of the Act until registration, and no action shall be sustainable, nor any penalty recoverable, in respect of anything done before registration.

The Committee feel that this query involves a point of con-

siderable difficulty; for the first section of the statute vests the sole and exclusive right of copying and multiplying, *inter alia*, the photograph and the negative thereof in the author for the term of his natural life, and for seven years after his death, or in the person for or on whose behalf the negative of a photograph may have been made or executed. Now, when an unregistered work has been pirated, it may be contended that the proprietor of the copyright is entitled to vindicate his right; for the fourth section, which requires registration, speaks of the proprietorship of copyright as a fact apparently anterior to the registration which it requires. The Committee do not give any certain opinion on this subject, but submit that it ought not to be taken for granted that our courts of law might not sustain an action for damages for the piracy of unregistered copyright.

Much light may be gathered on the question from the state of the law of piracy of unregistered books. No failure in making the entry at Stationers' Hall, required by the statute, affects in any manner the copyright of books, but only subjects the person making default to the penalty under the Act. It is true that this provision is specially contained in the statute; but it is important to state that, prior to the statute, the Court of King's Bench unanimously held that an action for damages might be maintained for pirating a work before the expiration of twenty-eight years from first publication, although the work was not entered at Stationers' Hall, and although it was first published without the name of the author affixed. (Beckford v. Hood, 7, T. R., 620). And in a prior case (Tonson v. Collins, 1 Blackstone's Reports, 330), Lord Mansfield said—that it had always been helden that the entry in Stationers' Hall was only necessary to enable the party to bring his action for the penalty, but that the property was given absolutely to the author, at least during the term. It is to be observed, however, that the statute requiring the registration of books imposes the obligation of registration in Stationers' Hall as a duty, for failure of which penalty is paid; whereas, the statute conferring copyright on photography appears to regard registration as a privilege of the author or proprietor. The Committee accordingly incline to the view that registration is necessary to give validity to the copyright of a painting, drawing, or photograph.

[The committee, in discussing this question, seem to have overlooked the final sentence in the 4th section of the Act, which runs thus:—"And no proprietor of any such copyright shall be entitled to the benefit of this Act until such registration, and no action shall be sustainable, nor any penalty be recoverable, in respect of anything done before registration."]

QUERY III.

Has the Photographer a Right at Common Law to make any use of an Unregistered Negative?

This question seems to have been already answered under the first query. If our observations there are correct, the photographer has only a limited right of property in the negative, which does not permit him to make any use of it inconsistent with the purposes and wishes of the person for whom it was executed.

QUERY IV.

Suppose the Photographer Registers a Negative without the Knowledge of the Employer, would he be Entitled to the Copyright?

The photographer who registers a negative without the knowledge of the employer has no title to the copyright, and is not proprietor thereof under the statute; for, under the provisions of the first section of the statute, he does not retain the copyright, except under a written agreement with the employer.

QUERY V.

If a Registered Photograph be not Marked as Registered, is there a Penalty for Infringement?

The statute does not require any mark to be impressed upon a registered photograph. It is the fact of registration in terms of the statute that secures the right of property, and therefore the penalties may be incurred though there be no mark impressed on the photograph.

QUERY VI.

If a Negative be Unregistered, and Prints from it Published, may the Work be Copied and Reproduced?

The principle of this question has been discussed in the obser-

vations under Query II., in which it has been shown that it may be contended that a right of property may exist without registration. But so far as the scope of the present statute may be held to determine the point, the Committee think that this query should be answered in the affirmative, provided that no name, initials, or monogram be affixed to the copy. The existence of these upon the photograph is sufficient to bring the copier within the penalties of fraudulent productions and sales of the 7th section of the statute.

[See our remarks on Query II. The 7th section only prohibits the fraudulent copying of name, monogram, or initials.]

QUERY VII.

May a Photographer Copy and Produce for Sale a Proof before Letters of any Engraving?

Two important general questions occur under this query. The first is:—Do the engraving statutes protect engravings which do not contain the name of the proprietor and the date of the publication engraved on each plate and printed on every print?

The second question is:—Assuming that these statutes do protect such engraving, does the copying of an engraving by the art of photography come within their intention?

As to the first point. The first statute protecting engravings is the 8th Geo. II., cap. 13, entitled an "Act for Encouragement of the Arts of Designing, Engraving, and Etching Historical and other Prints," which recites that divers persons have, by their own genius, invented and engraved sets of historical and other prints, in hopes to have reaped the sole benefit of their labours, and that printsellers and other persons have of late frequently taken the liberty of copying, engraving, and publishing base copies of such works and prints to the very great prejudice and detriment of the inventors and proprietors thereof. For remedy thereof, and for preventing such practices for the future, the Act vests in the inventor and engraver the sole right and liberty of printing and reprinting the same for fourteen years, to commence from the day of the first publishing thereof; the date to be engraved, with the name of the proprietor on each plate, and printed on every print. It is the latter words which give rise to the question now under discussion.

The next Act is the 7th George III., cap. 38, and is an amending statute of the former Act. It is observable that this Act does not expressly require the name of the proprietor and the date of publication to be engraved on the print, but it seems probable, as it is merely an amending Act, that the provisions of the previous statute (8th George II.) in that respect should be considered as included in the latter. Now it appears that there is a difference of opinion in the authorities as to the true construction of the statute—some holding that the date and name are not essential, others that they are. In a case in 1792 this contrariety of opinion comes out, but the case referred to was not decided on the point in question. At a subsequent period, Lord Ellenborough said:—"Although the plaintiff's name is not engraved upon the prints, if there has been a piracy I think the plaintiff is entitled to a verdict. The interest being vested, the common law gives the remedy." In a subsequent case, however, the Court of Common Pleas held both date and name to be essential to make the copyright of an engraving valid.—*Newton v. Cowie*, May, 1827, 4 Bingham, 234.

This difference of judgment may well make the Committee hesitate to give any opinion of their own; but, so far as they can venture to do so, they think the date and name to be essential, and that however contrary it may be to the principles of equity to infringe the rights of another engraver, the law will not prevent the piracy or inflict penalties on the infringer when the date and name do not appear on an actually published engraving.

As to the second question, the art of photography is so recent, and of a character so different from any former mode of copying and multiplying the work of the engraver, that it is not surprising that a judge presiding at a late trial by jury ordered the point to be reserved for after discussion. The Committee, however, observe that the words of the statute are very general. In addition to the special words, "engrave, etch, or work," there occur these words, "or in any other manner copy." These are so general that, though the Act was passed more than a hundred years ago, as it is still in active operation it must apply to the changing forms of art and the advances of science. Yet it must not be forgotten that if the engraver may

pirate an engraving which does not contain the date of publication and the name of the proprietor, much more will the photographer who prints off his copies from a proof before letters be free from any penalty.

[The point raised in the second question here has since been decided to the effect that photographic copies are prohibited by the Act.]

QUERY VIII.

Was there, prior to the recent Act, any Copyright in any Painting, Photograph, or Drawing? And are Paintings and Photographs Made or Executed prior to the Act in any way now Protected?

The Committee are of opinion that there was no copyright in any painting, photograph, or drawing prior to the recent Act. Its preamble so states the law. The Lord Chancellor, in moving the second reading of the bill in the House of Lords, while he paid a well merited compliment to the position and the labours of artists, stated that he could see no distinction between paintings and literary productions; that if the one was entitled to be considered property the other was also. Of course there is a right of property in these works so long as they are unsold or unpublished; but the distinction between the two things must be always kept in view.

In like manner, paintings and photographs sold or disposed of before the commencement of the recent Act are not protected by statute in any way. But though made or executed before the commencement of the statute, if they were not sold or disposed of prior to its date, they are protected.

QUERY IX.

Is Attendance by the Proprietor or his Agent at Registration necessary?

The statute does not expressly require that there should be personal attendance; but it is a regulation which the registrar may be entitled to make. Photographers scattered throughout the country are thus obliged to employ an agent in London to register their photographs.

[The necessity of a cash payment, the registrar declining to receive stamps, &c., and the various verbal explanations which arise, render some personal attendance necessary, and this has induced our publisher to undertake the necessary agency].

QUERY X.

May an Engraving be Photographed Simply for the Purpose of Producing Transparencies, and not for Sale?

A very nice question arises whether the statutes have given any remedy in the circumstances stated in this query. The statute which hits against the practice—if it does so at all—is the 17th Geo. III., cap. 57, which enacted that if any engraver, printseller, or other person shall engrave, etch, work, or otherwise or in any other manner copy in the whole, or in part by varying, adding to, or diminishing from the main design, or shall print for sale, or shall publish, sell, or otherwise dispose of, any copy or copies of any print whatsoever, such proprietor may, by action upon the case, recover such damages as a jury shall give or assess.

Part of the above statute, it may be contended, seems to stand disjunctively in the context, and to create a separate offence from that of printing for sale, or selling, which is prohibited in the clause immediately following. If so, then the mere copying of a print gives the proprietor a right of action without any sale, and he may show his damages to have accrued from exhibition, or from injury to his reputation, or interception of his profits. On the other hand it may be contended that the statute does not apply to a case where there is no intention to print, publish, or sell, but only to exhibit in a certain manner; that exhibiting for amusement is in no way analogous to selling a copy of a print; and that the transparency exhibited being in different materials and of different dimensions from the original print, makes a case which the statute does not contemplate. A judgment of Vice-Chancellor Shadwell supports the latter view. But the Committee do not consider the question finally determined by the opinion of that Judge, and do not wish to express a certain opinion upon this nice question; but, having stated both sides of it, leave it for the consideration of the individual members of the Society.

[The principle here supposed, namely, that *sale for profit*

constitutes the gravamen of the offence, is negated by a decision, *Novello v. Ludlow* (12 C. B. 177), which regards *gratuitous* distribution of copies of a copyright work as an infringement.]

QUERY XI.

May One who Photographs the Portrait of Another without his Knowledge Publish such Photograph?

This question does not involve any point of importance. It appears to the Committee that it is always a question of circumstance whether it may be done with impunity or not. Suppose a landscape be taken while there stands in some part of it an individual of fame or notoriety; he surely could not object to appearing in the scene, for his presence there was a mere accident, or the artist meant nothing but to do him honour. The opposite doctrine would exclude the photographer from taking a view of any public ceremony or historical event. On the other hand, if the object be to hold up some one to ridicule, or to represent some one to his disadvantage, the photographer might be interdicted, or damages obtained from him. The head of the famous Mr. Spurgeon upon the body of the gorilla was probably considered by that gentleman himself, his friends, and the public, as a good joke; but a satirical representation of Mr. Spurgeon, meant to injure him, to cast doubts upon the sincerity of his religious profession, or otherwise affect his efficiency as a clergyman, would undoubtedly be illegal and improper.

Although criminals be photographed against their will or without their knowledge, and copies of their portraits circulated among the police of the country, they can have no right to object to such a proper use of their portraits as enables the authorities to detect crime; for every course that may be necessary in the judgment of the officials responsible for the detection of crime would be justified, on the same principle that no claim of damages lies against those at the instance of one accused of crime and afterwards found innocent.

The Committee cannot conclude without expressing their regret that the Statute has not been framed with such perspicuity as it might have been, and that doubts as to its interpretation on some points may be entertained. This arises from the fact that the registration clause in the Bill which was first read in Parliament was framed quite differently from the mode in which it now appears in the Act of Parliament. The Bill underwent many modifications in its clauses while passing through both Houses, and hence arises the difficulty of construction. The Committee, however, have been informed that there is a prospect of another Photographic Bill this session of Parliament, promoted by artists and engravers, which, it is hoped, will put an end to many vexed and doubtful questions.

[Signed.]

ANDREW MUIR, Chairman.

MEMORANDUM OF THE SALE OF A NEGATIVE PHOTOGRAPH, RESERVING THE COPYRIGHT TO THE PHOTOGRAPHER.

Stamp, 6d.

A. B., Photographer, having sold and disposed of the negative of a photograph [here describe it] made and executed by him, to C. D., it is hereby expressly agreed upon that the copyright thereof is retained by and reserved to the said A. B.

This memorandum is made in terms of the Act 25 and 26 Vict., cap. 68, and signed by the said C. D., at _____, the day of _____, 186 .

A. B., Photographer, having, for a good consideration, made and executed for and on behalf of C. D., the negative of a photograph, of [here describe it]—it is hereby expressly agreed upon that the copyright thereof is retained by, and reserved to, the said A. B.

This memorandum is made in terms of the Act 25 and 26 Vict., cap. 68, and signed by the said C. D., at _____, the day of _____, 186 .

MEMORANDUM OF ASSIGNMENT OF COPYRIGHT.

Stamp, 6d.

I, A. B., proprietor of the negative of a photograph of [here describe it]—and registered in my name as proprietor thereof, in the Stationers' Hall, on the day of _____, 186 , in terms of the Act 25 and 26 Vict., cap. 68, hereby assign to C. D. the said negative photograph and copyright thereof.

This memorandum of assignment, made in terms of the above Act, and signed at _____, the _____ day of _____, 186 _____.

I, A. B., Photographer, having, for a good consideration, made and executed for and on behalf of C. D. the negative of a photograph of [here describe it]—it is hereby expressly agreed upon, that the copyright thereof is to be retained by and reserved to the said C. D.

This memorandum is made in terms of the Act 25 and 26 Vict., cap. 68, by me, the said A. B., and signed at _____, the _____ day of _____, 186 _____.

MEMORANDUM OF SALE OF NEGATIVE OF PHOTOGRAPH,
RESERVING THE COPYRIGHT TO THE VENDEE.

Stamp, 6d. Vict. 23, cap. 15.

I, A. B., Photographer, having sold and disposed of to C. D. the negative of a photograph of [here describe it]—made and executed by me, it is hereby expressly agreed upon that the copyright thereof is to be retained by and reserved to the said C. D.

This memorandum of sale is made by me, the said A. B., in terms of the Act 25 and 26 Vict., cap. 68, and signed at _____, the _____ day of _____, 186 _____.

NOTES ON THE COLLODIO-ALBUMEN PROCESS.

BY W. D. CLARK.*

AFTER stating that the negatives of some charming views of Edinburgh, &c., which we have before had occasion to praise in these pages, were all by the collodio-albumen process, as described by Mr. Mudd, Mr. Clark proceeds:—

Good negatives may be got by this process with a very wide range of exposure, as the development may be varied to meet the greater or less degree of light; but it is a great comfort to have the plate well exposed, and it is better to get a plate over-exposed rather than under-exposed.

My Edinburgh views are 9 inches by 11, a quarter of a sheet of paper. For this size, with a fair light, ten minutes is a good average exposure for buildings, and fifteen to twenty minutes for subjects composed chiefly of trees. Many members of your Society practise the wax paper process: a good rule to begin with would be to give half the exposure required for wax paper.

I dare say you will remember how pleased I was when you first showed me your camera, copied from Mr. Kinnear's, and how you kindly undertook to get one made for me. As soon as I received it, I sent it to Mr. Mudd's rooms, so that it might be seen. He and other friends in this district adopted it, and we have all used that form ever since in our excursions, and feel indebted to that gentleman for having given us so handy an instrument. When in the border country, last autumn, with a friend, who is an admirable photographer, he remarked that he never put up his camera without being struck with the ingenuity displayed in its contrivance.

I fancied that a light lens might be best suited for so light a camera, and so adopted Ross's orthographic, which had just then been introduced. I used it alone for two seasons, and found, in addition to the advantage of straight marginal lines, that a pretty large stop could be used with it in dark weather, without much loss of definition. Many of my Edinburgh views were done with this lens; but as it does not give quite the same sharpness for ordinary landscape work as the old single lens, I added to the camera one of the Lerebour's lenses with rather a sharp focus, that Mr. Mudd got made with the special view of being used with Mr. Kinnear's camera.

I am now having one of Dallmeyer's 8 × 10 triplet lenses fitted to the same camera, so as to get the advantage, when desirable, of the wide angle of view this lens includes.

As each kind of lens has special advantages, I think it of great importance to have more than one lens fitted to the same camera when aiming at first-rate work.

Every one knows the distortion got by tilting up the camera in architectural subjects. This is very decided in my print of the door of Holyrood Abbey. I think a very simple way of getting rid of this defect with a Kinnear's camera is to have the front part that carries the lens so arranged that it can be turned back and fixed at any angle that may be necessary. By this means the camera is always kept, as it should be, hori-

zontal, and only the lens is turned up towards the subject.* This is much simpler than tilting the camera up and then adjusting a swinging back with one's head beneath the focusing-cloth. The tilting of the camera is always an awkward operation. Another advantage of this method of turning back the lens is, that when you have very near and distant objects in your subject, you can get both well in focus. A 15 × 12 camera I have, made by Mr. Nelson of Edinburgh, has this plan carried out very ingeniously; and I find that with a Petzval lens I get the flowers in my garden and the hills three or four miles distant all quite perfect in focus at the same time.

Last summer I worked a good deal with Dallmeyer's small triplet lens, fitted to a folding camera 5 × 7 inches. This is a most convenient instrument for an amateur working with dry plates. The pictures it gives are very beautiful; and eight plates may be carried in four double slides with ease, in a leather case that also contains the camera. I carried this little apparatus over some of the roughest ground in the Highlands, without being incommoded with it. I shall send you a few specimens along with this, to show what can be done with this portable little instrument. Mr. Dallmeyer tells me that my negatives will bear enlarging to 15 × by 12 inches; and I intend to attempt this with a lens he is now making.

[Mr. Clark, after describing the details of exposure, &c., of several of his pictures, proceeds to make some remarks upon the critics who have at different times commented on his pictures, in which he displays an amusingly thin-skinned irritability. A contemporary had, for instance, praised the photography, but condemned the point of view, and Mr. Clark crushes him by saying that he had had the assistance of two of Scotland's best landscape painters in selecting the point of view; but he forgets that even that might not prevent it from being bad. He then tells a story, which sounds very like a *canard*, illustrating the comical ignorance of some critic who had gone from London to Manchester to report upon an exhibition, but who absolutely did not know of the existence of a Royal Scottish Academy! Mr. Clark's pictures are for the most part good, and he appears a shrewd and intelligent man, although he talks some nonsense about the critics. But he and all exhibitors should remember that an adverse criticism cannot make a good picture a bad one; and that if the public examine a picture condemned by the critics and find it good, they cease to trust that critic, so that incapable or dishonest criticism rarely either serves any journal or damages any artist. Criticism cannot always be perfect, but we believe it is for the most part both honest and just.]

I have practised three modes of development. So far as I can judge, they all give equally good results. I first use gallic acid, just as for wax paper. For this method it is desirable that the plate should be well exposed—if it is not so, the development is very tedious. A convenient way of conducting this is to have a saturated solution of gallic acid in alcohol. Pour as much of this into a quantity of water as will make it taste distinctly bitter. Put your exposed plate into a flat glass dish; add a very little nitrate of silver, without any acid, to your solution of gallic acid, and fairly cover your plate with this. If the exposure has been satisfactory, you will be able to see your subject pretty distinctly in about ten minutes, and the process will be finished in from half an hour to an hour. I like to develop a picture slowly, for by that means you get a great deal of detail that you will lose if you blacken the plate quickly by using nitrate of silver liberally to begin with. It should be remembered that it is the *gallic acid* that develops. The silver merely *blackens* what has been developed. For this reason it is proper to add so little silver at first, that the picture comes up of a *brown* colour; and when *all* the detail is fairly out in *this* way, add more nitrate of silver, and the plate will rapidly blacken without becoming dirty, or deposit forming in the solution. No acid is necessary in this process.

If the plate is under-exposed, the development will be very slow. In this case, it is better to wash the plate and develop by a more energetic method.

I used generally to develop from four to six plates at the same time, in as many dishes. They require very little attention—only an occasional shake to prevent the development on the sky

* We suggested an arrangement for this purpose to Mr. Meagher some years ago, who carried it out in a camera for use, and manufactures them so to order.—Ed.

* Condensed from a Communication addressed to the Photographic Society of Scotland, and read April 14th.

assuming a crystalline form, somewhat like water when it is freezing.

A convenient and cleanly method of raising the plate from the glass dish, for the purpose of noticing how the process is going on, is with a bent silver wire.

It is during development that the great advantage of collodio-albumen over other dry processes is found. The surface of the plate is a *hard* one. Whenever any markings or stains are noticed, stop the development, pour plenty of water over the plate, and rub it till clean with a tuft of fine cotton-wool; then proceed with the development as before. In rubbing the plate, a circular motion is best. It is astonishing the amount of friction a plate properly prepared will bear. Duck eggs give a particularly hard film. Of course no sand or grit must be in the cotton or water, or the plate will be scratched. The fingernail will also scratch, but that is easily avoided.

To develop with pyrogallic acid, place the plate on a stand and moisten it with water. I have used various kinds of stands, but like none so much as the large glass goblets used in Scotland for making toddy. Placed in a flat porcelain dish, it is easily made level by packing the dish beneath with bits of paper or cloth. A round stand, such as this, is more convenient to tilt the plate than from a triangular one. Mr. Mudd has a round stand, manufactured of brass, with a heavy foot. It is very good and convenient; but I prefer the toddy-tumbler, as it can be so easily and perfectly cleaned. All metal stands, too, have the objection of decomposing the developer, if it comes in contact with it, when it contains nitrate of silver. Well, when the plate is moistened, pour the water off; take a solution of pyrogallic acid (say, of two grains per ounce), add a few drops of a rather weak solution of nitrate of silver (say, ten grains per ounce), with one-third or one-half of its weight of citric acid added. Pour this on and off the plate till the details of the picture are well out—of a feeble brownish colour; then add more of the silver solution to the developer, and the plate will blacken rapidly. The developer will probably get dirty before the picture is out; if so, throw it away. Wash the plate *well* with plenty of water and a tuft of clean cotton. Mix more of the developer in a clean glass, and proceed as before. Do not push this process too rapidly, if you want a delicate negative full of detail. Fifteen to twenty minutes are a fair time.

A very elegant modification of this process was introduced by Mr. Wardley, of Mr. Mudd's establishment. I think it the best at present known. He found that when pyrogallic acid was used quite alone, and other acids kept away, the plate developed easily and clearly. The plate is afterwards blackened by silver.

To work this process, take a solution of pyrogallic acid, of almost any strength—say from two to twenty grains per ounce. After the plate is moistened with water as before, pour on and off with this solution till the subject is pretty fairly out. The colour of the negative will be very faint and feeble. It is then blackened up by adding to the same pyrogallic acid some nitrate of silver containing citric acid (say half its weight of acid), and pouring on and off till the desired depth is obtained.

This process can be made to work very rapidly by using the water hot—say, from 120° to 140° Fahr. The plate may be brought up to this temperature by pouring plenty of water over it, or, as I generally do, by placing it over a sand-bath. The warm solution of pyrogallic acid must be spread over the plate very rapidly, as the picture starts out almost instantly. This is the proper process for plates that have had short exposures. All the little (5×7) prints I send, with exposures of one minute or under, have been developed in this way—that of St. Mary's Loch, for instance—nothing can be done more perfect than the detail of the dark pine-tree in the foreground; and in the negative the detail is perfectly given of trees and farm-house on the margin of the lake, with their reflections in the water; but unfortunately such distant objects are greatly lost in a paper print; they all show till the print enters the hyposulphite. As you well know, such delicate gradations suffer much in the fixing. I think this little print shows what an admirable lens Dallmeyer's triplet is.

One of the most difficult things in photography is to know how far to carry the development. The difficulty is increased by the variability of the light in the operating-room. Looking through the negative, its density appears greater or less according to the strength of the light outside. Of course, the beauty of the print depends on the negative having the right density. The best plan is that proposed first by Mr. Mudd, of

having a good negative in the room beside you to compare with. In collodio-albumen the development can be carried further after fixing, provided all the hyposulphite has been *completely* washed off the plate; and if a negative be too dense, it can easily be reduced by placing it in a dish with a very weak solution of iodine in iodide of potassium. Watch the plate carefully till you think a sufficient quantity of the silver has been converted into iodide of silver. Wash, then dissolve out the iodide by means of hyposulphite of soda, and wash again.

In fixing, never employ cyanide of potassium, as its strong alkaline reaction destroys the albumen. Use hyposulphite of soda, from 4 to 6 oz. per pint, and add sufficient acid (say, muriatic or acetic) to make the solution distinctly acid to test-paper.

Mr. Sutton has said that painting out skies is one of the immoralities of photography. If this be true, I am a most immoral photographer; for I think a negative not worth much if it does not require the sky painting out, either wholly or in part. If the sky be deep enough to resist the light, it is either over-developed or it has not been sufficiently exposed; and it will print hard—black and white, and without the delicate gradations that are the chief charms of a good photographic landscape.

I do not think we will ever be able, in ordinary landscape work, to get clouds and the landscape at the same time; for if the exposure be such as to get the clouds perfect, the landscape is greatly under-exposed. I have seen some pretty fair attempts, but they were only tolerable, done by a kind of compromise—the exposure too long to get the clouds perfectly, and too short to get satisfactory detail in the landscape. The sea-shore views are a kind of exception, because there you have only sea and sky, and the difference of light on the two is much less than in ordinary landscape. Of these, the pictures on glass by Mr. Breeze are probably the best; but in them, where there is a bit of rock, or boat, or other solid matter, it is under-exposed; only the clouds and sea are perfectly given.

The absence of clouds is one of the greatest defects in landscape photography; but here composition pictures are quite legitimate—one negative for the landscape and another for the sky. This certainly increases the trouble of printing considerably; but I fear it is the only way to overcome the difficulty.

If we look at the engravings from the works of an able artist, such as Turner, and suppose the clouds removed and replaced by a simple wash of grey, we at once see that the beauty of the prints would be destroyed. In like manner, I think if we can add appropriate clouds to our photographic landscapes, we shall greatly increase their interest.

I send you two or three small examples to illustrate this. From each negative there is a print, with and without clouds. The clouds are printed in from two negatives, taken at the coast by my friend Mr. Sidebotham, of The Strines. You will notice how much additional character and expression is given by the clouds, and how much they increase the idea of space. This is perhaps especially the case with the view of Smalholm Tower. The sky has been printed so as to give a wild look to it, in keeping with the solitary rootless tower reflected in the little loch. I must mention that the negative of the landscape in this case is also by Mr. Sidebotham, taken during a little excursion we made together into the Border country last autumn.

There is an advantage contingent on printing the sky from a separate negative. A photographer has often to wait a considerable time for suitable weather to take his views; but if, in addition, he had to wait for clouds that would form an agreeable composition with his subject, the difficulty of doing much would be greatly increased.

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this society was held in the City of London College, on the evening of Thursday, May 14th, the Rev. F. F. Statham, M.A., F.G.S., in the Chair.

The minutes of a previous meeting were read and confirmed. Mr. MARTIN exhibited some brilliant prints on resinized paper, produced by Messrs. Horne and Thornthwaite, with decolourised resins. A plan had also been adopted of keeping

the solution on the surface, and so producing with the dead surface a brilliancy almost equalling that of prints on albumenized paper. He was not in a position to communicate the details of the method employed to the meeting.

Mr. HARMAN exhibited some fine card portraits on enamelled paper.

Mr. HARMER then read a paper "On Double or Fancy Printing," (see p. 243) in the course of which he illustrated the mode of manipulating he employed in the various stages of the operations described, and also the kinds of masks employed and the mode of preparing them. He also referred to the recent allusion of our American correspondent to some moonlight scenes produced in Philadelphia by composition printing, and said that he had tried similar effects some time ago, and now produced some negatives consisting of clouds and moon simply drawn with a black lead pencil.

Mr. A. H. WALL said that whilst looking at Mr. Harmer's masks he had been struck with the fact that the plan adopted might possibly be made to have a wide and useful application in the industrial ornamental arts, in producing designs now obtained by the more expensive process of engraving. As to the use of a method of introducing ornamental borders to photographs he thought it was a dangerous suggestion, and he was always sorry to see a power put into the hands of photographers which was so liable to abuse, and with which they were so liable to make a mess. He had laughed heartily at the American notion of a white paper moon. Cloud negatives to produce the effect referred to ought to be carefully prepared by artists from photographic studies; but he could not help feeling that some of Mr. Harmer's suggestions put a dangerous power into many hands who would abuse it.

Mr. G. WHARTON SIMPSON remarked that in all things a power was, in proportion to its capability of good, effective in bad hands for evil. He thought, however, it was scarcely wise or desirable to deprecate the use of Mr. Harmer's method because it was capable of abuse.

Mr. WALL did not wish to do that. He had been going to add that the method which appeared undoubtedly to have been originated by Mr. Harmer was accredited in various portions of the newspaper press to Messrs. Dickenson who obtained considerable praise for the artistic effect produced.

The CHAIRMAN thought it a pity that the old adage, *palman qui meruit ferat*, should be forgotten in such matters; Mr. Harmer was certainly deserving of much credit for the ingenuity shown, and the admirable results obtainable with a comparatively small amount of labour.

After some further conversation and examination of specimens,

Mr. HART exhibited a printing frame which he had devised some years ago for facilitating double printing, of which we shall give a detailed description in our next.

Mr. G. WALLIS, the inventor and patentee of the system of autotypography, recently described in our pages, and the possible combination of photography with which we suggested, attended this meeting for the purpose of exhibiting some of his productions, explaining his views of the photographic bearing of his invention, and hearing any suggestions on the subject. He said that, as an artist, he had long felt the want of some method by which an artist could himself execute a drawing to be multiplied by the printing press, without the intervention or translation of another mind and hand, as was now necessary in engraving. He then entered into a brief history and description of his invention, all details of which will be found in his paper in our pages a few weeks ago. He then proceeded to state what the conditions were, which in photography it would be necessary to secure, in order to make it available in connection with his process. An image in some definite relief, however small the amount, in a hard concrete substance on a textureless surface was necessary. The bed of his machine was of glass, and it was possible that it might be used to receive the image. Or it might be produced on gelatine paper, prepared with collodion varnish, to render it waterproof. The amount and kind of relief must be such as would produce in the intaglio, produced on the surface of the metal plate, sufficient holding power for the ink, so that it would not wipe out. He scarcely hoped that it would be possible to produce an impression so perfect and complete by photography, that it would not require touching at the hand of the artist. But he thought if an impression could be produced, which should be 75 per cent. photography, and 25 per cent. the touch of the skilled artist, something very valuable both in truth of result and in economies would be gained.

The great advantage of his method was found in the fact, that, when a photographic impression as perfect as possible was obtained, it might be finished by the artist's pencil with the proper ink very easily, and then a complete plate produced by his machine. This was just the point in which the processes of Pretsch and others had failed: any re-touching their productions required must be done with the graver on the metal plate, which was much more difficult and costly than his method of working on the impression from which the plate was to be produced. He expected that photography would fail to give the deep forcible shadows which gave vigour to the result; he referred to those parts produced by what engravers called the deep digs. This, however, could be supplied by hand. He had already produced a plate from a photographic impression of an engraved plate, from one of Raphael's drawings, and he believed if those more skilled in the details of photography were to give the matter proper attention it would soon be done. Indeed, if he had time to devote to the matter, he thought he would be able to produce a photographic plate by his method in fourteen days from that time.

The CHAIRMAN, proposing a vote of thanks to Mr. Wallis for his interesting description of his beautiful process, asked him if he had tried to produce an impression from a Daguerreotype?

Mr. WALLIS said, "No;" but to clear the ground he might state what he had done. He had taken a mixture of starch, gum, bichromate of ammonia, and Paris white, with these he had coated paper in a dark place, and had then submitted this under a negative to the action of light. Those parts on which the light had not acted were, of course, soluble, and were easily washed away, whilst that on which light had acted was insoluble, and remained on the paper in relief, capable of giving an intaglio image on his plates. A difficulty in the way of using paper from the fact that its texture was reproduced, giving a grain. This might be dealt with by burnishing out the high lights, as in mezzotint engraving. If the photographic image could be produced on gelatine paper, it would then be in the same condition as his drawing.

Mr. SIMPSON explained, in reference to the question about the Daguerreotype plate, that it presented an image less in relief, perhaps, than any other kind of photograph, except ordinary prints. The ordinary collodion image, especially, when forced a little in intensifying, possessed a very palpable relief; but whether of the right kind for the application in question seemed uncertain. There were various other methods of obtaining the image in relief. Several very ingenious methods were described in a very elaborate specification of a patent by Mr. Joseph Lewis, of Dublin. Those interested in the subject might consult that specification with advantage, and if the methods there given were available here, their use might easily be made the subject of arrangement.

Mr. WALL thought the very great number of tones, and the delicate gradation of photographs, would be difficult to render in such a manner.

Mr. WALLIS said they were there to look at the difficulties, and, if possible, overcome them.

Mr. SIMPSON said he thought that Mr. Wall's objection was largely met by the former remark by Mr. Wallis, to the effect that perhaps 25 per cent. of artistic manipulation must be added to complete the 75 per cent., which had been obtained from the photograph. It was clearly true that as the gradations of a photograph were not like the conventional rendering of gradation obtained by hatching, stippling, lines, &c., a difficulty was interposed, as these methods seemed almost necessary in impressions to be printed. But a few touches of the artist upon the image already rendered by the photograph, might give very effective pictures.

Mr. WALL thought the process would, not render the more delicate gradations of photography.

Mr. WALLIS thought it would, and showed drawings in which touches of great delicacy were rendered, and to these might be added the forcible touches given by what Mr. Simpson had well called the conventional mode of rendering gradation.

A conversation on the subject followed in which Messrs. Wallis, Sebastian Davis, Wall, Harman, Simpson, and others took part.

Mr. MARTIN said he thought sufficient emphasis had not been laid on the introduction of oxides of manganese and tin to the ink to give hardness to the image.

Some conversation on this point followed, and on the use of some suitable metallic oxide in getting photographic images in relief, &c.

In answer to a question by Mr Simpson on the subject of the hardening of the plates, by the acrierage process, Mr. Wallis said when this was done, 2000 impressions might be produced easily from one of the plates.

In answer to a question as to the composition of the ink which gave the drawing in relief, Mr. Wallis stated it consisted of Indian red, rice starch, gum, oxide of tin, Paris white, and bichromate of ammonia.

Mr. SIMPSON observed that it was somewhat singular, that in a somewhat remote degree this was already a photographic process, as the action of light on bichromates, in combination with organic matter, was one of the conditions necessary, as it hardened and rendered insoluble the ink by which the drawings in relief were produced.

Mr. WALLIS said he had no hesitation in saying that without the knowledge of the properties of certain bodies introduced by photography, this process would have been impossible.

After some further conversation the subject was concluded.

Mr. SYDNEY SMYTH exhibited a parcel of very fine negatives produced by the intensifying process with iron and citric acid, recently described in the PHOTOGRAPHIC NEWS.

After some routine business in reference to the election of officers at the ensuing annual meeting,

The CHAIRMAN announced that it was hoped the two presentation prints, one a figure study, by Mr. Rejlander, and another a fine landscape, by Mr. Henry White, would be ready at the next meeting.

It was announced that at the next meeting Mr. Leake would read a paper on the intensifying of negatives, after which the proceedings terminated.

PHOTOGRAPHIC SOCIETY OF SCOTLAND.

THE Photographic Society of Scotland which twelve months ago seemed in danger of dying of inanition, resolving to meet once in two months instead of monthly as before, seems recently to have been unusually active and its proceedings very interesting. We find in the last number of its organ, the *Photographic Journal*, copious accounts of two meetings held in April and May respectively, from which we condense the following, and also reproduce the most interesting papers on another page.

An ordinary meeting was held April 14th, Mr. George Moir in the chair. After some routine proceedings the Honorary Secretary read the following.

REPORT OF THE PRIZE COMMITTEE.

THE Committee have endeavoured, to the best of their ability, to discharge the duty devolved on them, which they have found to be a difficult and delicate one.

They recommend that the prize for the best portrait or group be given to Mr. Robinson's, of Leamington, "Bringing Home the May."

At the same time, the Committee have some doubts whether any fair comparison can be instituted between such elaborate compositions and single figures or groups. They would, therefore suggest to the Society that in future the medal should be given for the best portrait or group taken direct by the camera at one operation.

Laying aside Mr. Robinson's picture, the Committee would have found great difficulty in deciding between the competing claims of Mr. Tunny, who contributes a beautiful portrait of a young gentleman, and some of the admirable small portraits of Mr. Rodgers, of St. Andrews.

In landscape photography, the Committee have found the merits of Mr. Maxwell Lyte's Pyrenean landscapes, and the charming English landscapes of Mr. Vernon Heath, so equal, though in different styles, that, as the only practical solution of the difficulty, they would recommend that a medal should be given to each; the "Lac d'Or" being selected as, on the whole, the best picture by Mr. Maxwell Lyte, and "Near Burnham, Bucks," as the best by Mr. Vernon Heath.

They would also beg leave to mention, as following close on the two names already mentioned, the contributions of Mr. Mudd, Mr. Annan, and Mr. S. Thompson.

For printing in carbon, the Committee would recommend that the medal be given to Mr. Pouncy, of Dorchester, for his view of "Melrose Abbey," in which, it appears to the Committee, he has overcome the difficulty of representing in carbon every variety of shade and tint exhibited in the original negative. At the same time the Committee trust that Mr. Pouncy will be stimulated by this award to perfect his most important discovery, and not rest satisfied till he is able to compete in

delicacy of tint and pureness of lights with prints produced by nitrate of silver, so as to make his process available either for landscapes or portraits.

In apparatus connected with photography, the Committee would desire to mention the beautiful cameras and lenses exhibited by Mr. Dallmeyer; but the only camera possessing peculiar merit is that by Mr. Meagher, the *binocular camera*, which comprises in itself all the best features of other cameras, and is suitable either for stereoscopic pictures, *cartes de visite*, portraits, or for views the whole size of the plate.* For this camera the Committee would recommend that Mr. Meagher receive a medal.

(Signed) 'GEORGE MOIR.

COSMO INNES.

T. B. JOHNSTON.

14th April, 1863.

The report met with the cordial approval of the Society. Some notes "On the Collodio-Albunum Process," by Mr. Clark, were then read, and illustrated by some fine photographs. After some other proceedings, the meeting terminated.

The annual meeting was held on May 12, Mr. C. G. H. Kinnear in the chair.

A paper "On Photography, as a Fine Art," by Mr. W. D. Clark was read; and also one "On the Curvature of the Image due to the Primary and Secondary Force of Oblique Pencils of Light, and on some other points in Photographic Optics," by Mr. R. H. Bow.

The silver medals of the society were then awarded as follows:—

For the best Portrait or Group.—Mr. H. P. Robinson, of Leamington.

For the two best Landscapes.—Mr. F. M. Lyte, Baguères de Bigorre, and Mr. Vernon Heath, London.

For Prints in Carbon.—Mr. John Pouncy, Dorchester.

For Photographic Apparatus.—Mr. P. Meagher, London.

The annual report was then read, from which it appeared that a balance remained in the hands of the treasurer amounting to £366 0s. 7d. It also announced that arrangements had been made with Mr. Vernon Heath, for a number of copies of his prize picture, "Near Burnham, Bucks," as a presentation print to the members.

The following gentlemen were then elected as officers for the ensuing year:—

President.—Sir David Brewster, K.H., F.R.S., &c., &c.

Vice President.—C. G. H. Kinnear; Horatio Ross.

Council.—Wm. Scott Elliot; Rev. D. T. K. Drummond; George Moir; James G. Tunny; Alex. Young Herries; J. Ramsay L'Amy; Major Bell; William Walker.

Honorary Treasurer.—H. G. Watson.

Honorary Secretary.—T. B. Johnston.

Honorary Auditor.—John Cay.

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, May 20th, 1863.

OUR sixth Photographic Exhibition opened its doors to the public on the 1st inst., although its arrangements were not fully completed, for no catalogue was ready, and new pictures are being added daily.

A very cursory inspection soon satisfies the spectator that Photographic art is in a rapidly progressive state. The immense diversity of subjects, and the extreme beauty of most of the pictures, is at first quite bewildering, and one cannot help pausing frequently, and asking, Can all this be photography, pure and simple?

Of portraits there are all sizes, from the miniature postage stamp and carte de visite, to the "enlarged" life size, each with its own peculiar and distinguishing excellencies. In fact, portraits predominate in this Exhibition, and in most cases excite strong interest, from the remarkable excellence of the pictures, even though the originals may be unknown. Foremost in this department of the art stands M. Adam

* This is the camera we designed for our own use two years ago, which was admirably carried out by Mr. Meagher, who has since manufactured it largely. See PHOTOGRAPHIC NEWS, p. 259, vol. v.—ED.

Salomon, whose productions are incomparable for vigour, brilliancy, and life. It is truly wonderful, and altogether inexplicable, how a photographer can so *create* his subjects, if I may so express it: how, if his art be so mechanical, as some maintain it is—how can this remarkable difference, in portraits especially, be attained. For, if the art were so very mechanical, all could and would attain to the marvellous results which M. Salomon wholly reserves to himself. There are some, however, who maintain that the portraits by this artist are elaborately re-touched, and their peculiar aspect would appear to warrant that assertion; if such be the fact, it would modify our admiration, but not detract from certain peculiar excellences. There are, however, many portraits by other artists which cannot lie open to this suspicion, and which serve by their intrinsic excellence to maintain the supremacy of this branch of the art. Angerer, of Vienna, exhibits a magnificent collection, and the works of M. Carjal are scarcely a whit less excellent, his portrait of Count Nieuerkerke is a triumph of photographic portraiture. The portraits contributed by M. Claudet have excellences peculiarly their own. M. Alophe and M. Thouvert also contribute some remarkably fine heads.

Among English exhibitors, the most prominent are Coloud Stuart Wortley and Mr. Robinsou; the former, by his magnificent marine views, in which Vesuvius in a state of eruption is most conspicuous; and the latter, by his large picture of "Bringing Home the May." This is regarded as the gem of the Exhibition.

The Exhibition is particularly rich in landscapes and fine architectural subjects. M. Cama's views in Egypt, from waxed-paper negative, which occupy a space of nearly seven square yards at the bottom of the room, have a most imposing effect. The pictures are remarkable both for their vigorous *chiaroscuro* and their delicate gradation of tone. The views in Spain, from negatives taken by the late Mr. Clifford, present us with many of the finest specimens of Arabic architecture extant. MM. Bisson Freres' Alpine views are, doubtless, familiar to you; they form a very prominent feature in this Exhibition. M. Nadar, who is equally at home in the clouds as under ground, exhibits some very interesting views taken in the Catacombs by the aid of the electric light.

The Viscount Aguado exhibits some interesting specimens of enlarged pictures, landscapes, and marine views. Of stereoscopic pictures there are but few, and those are for the most part the productions of MM. Ferrier and Soulier, who also exhibit some remarkable positives on glass.

Engraving by photography has arrived at a remarkable degree of perfection, especially in the hands of M. de la Blanchere and Baudvan. A series of seven portraits exhibited by them, whole-plate size, are truly surprising from their excellence in all artistic qualities, and they are, moreover, printed in carbon ink upon copper or steel plates. The enamel positives of M. Lafon de Carnassac have also acquired an extraordinary degree of delicacy during recent improvements. Most of the pictures are superior to those taken on paper, and are, moreover, of an imperishable nature.

Among the curiosities of this capital none is more interesting to the photographer than the establishment of MM. Delton and Co., styled the *Photographic hippique*, situated in the Avenue de l'Imperatrice, Champs Elysées. It is a charming spot, where a beautiful garden surrounds a spacious courtyard containing the accessories necessary to this kind of photography—stables, carriages, &c., a vast glass operating room, a charming greenhouse, splendid saloons furnished with magnificent albums containing specimens of portraits on horseback, &c., including most of the aristocracy of Europe. The ever active proprietor of this establishment fully aware of the necessity for novelty in sustaining in vogue, has recently patented a new kind of publicity by giving photographic representations of works of art, as well as of all kinds of mechanical and commercial productions, specimen cards, views of interiors of warehouses, mansions, houses, carriages for sale or to let, &c. This album thus

forms a most unique kind of advertising medium, and this may be regarded as one of the most ingenious and useful applications of photography to the ordinary business of life.

INSTANTANEOUS AND LANDSCAPE PHOTOGRAPHY.

DEAR SIR,—I omitted to state in my article on "Landscape and Instantaneous Photography," in the *NEWS* last week, that the effects of atmosphere are more *forcibly* given with my formula than with any other I have tried; I have always a decided objection to taking pictures when the wind is in the east, the fact of its being so, being plainly depicted in the resulting positives.

I also omitted to state that for interiors and very long exposures, I use Sutton's rapid dry collodion 20 ounces, Pouting's ordinary 10 ounces. I find the plate will keep after sensitizing full 15 to 20 minutes without deterioration. Trusting that these remarks may prove of assistance to amateurs and others, I remain, dear sir, yours truly,

W. H. WARNER.

IRON INTENSIFIERS.

SIR,—I was very pleased to see Mr. Blanchard's suggestion of an *iron* intensifier in No. 243 of the *PHOTOGRAPHIC NEWS*, and also your commendation of the same to your readers in your leader of the same number; for pyrogallic acid, although it is a very good intensifier, it is difficult to get pure; it is expensive, and its solution will not keep many days in warm weather. The fact too, of negatives intensified with iodine followed by pyro and silver (a very favourite method), being liable to darken gradually from exposure to sunlight, as proved by such good authorities, makes the introduction of a new intensifier the more important.

Without wishing to claim priority of invention in this, the credit or profit from which I do not care for, being only an amateur, I will lay before you a process very similar, but, I consider, superior, to Mr. Blanchard's, which I tried with success last season at Ventnor. If you approve of it you may give the photographic world through your columns the benefit of it; if not, consign this to your waste-paper basket.

With this long preamble here is my *modus operandi*. Collodion highly bromized; bath—neutral, or faintly acidified with nitric acid. After an exposure that most photographers would call *long*, I use this

Developer.

Protosulphate of iron	8 to 10 grains
Glacial acetic acid	30 minims
Alcohol	quant. suff.*
Distilled water	1 ounce.

When the details are well out this is tilted off, and without washing the plate, a second quantity of the *same* solution is applied as an *intensifier*, with the previous addition to it of a few drops of

Nitrate of silver	15 grains.
Citric acid	15 "
Distilled water...	1 ounce.

The desired intensity being obtained, if water be plentiful the negative is fixed with hypo and washed; but if that friend to the photographer, of every creed, be scarce, the plate is rinsed with one or two drachms of the precious liquid, flooded with glycerine, and carried home in one of Murray and Heath's "draining plate boxes," to be fixed at leisure.

This formula, founded on Major Russell's very excellent one for tannin plates, has, I think, great advantages, such as the use of the same solution as developer and intensifier, and having the same proportion of acetic acid and alcohol in each case the plate does not require any washing between the two operations; then the intensifying is slow and under control, and the deposit of silver very fine, giving beautiful delicacy in the negative.

* According to the age of the nit. silver bath.

I have deferred writing to you for two or three weeks hoping to get the leisure to try a few plates, by way of confirming my experiments of last autumn, but professional duties have so occupied all my time, and still do so, that I do not see any chance of being able to do this for some time, and therefore send the process just as it is, that it may be tested and discussed by more able photographers.

Hoping that I may have communicated one useful hint for the benefit of others, in return for the many which I have received through your valuable journal,—I am, sir, your obedient servant,
JOHN G. LIVESAY.

Talk in the Studio.

COLOURING PHOTOGRAPHIC PICTURES.—A patent has recently been taken in the United States for colouring photographic pictures on albumenized paper with dry colours. Such pictures, owing to the albumenized paper not being capable of receiving dry colours without some preparation, and no perfectly suitable preparation having been heretofore known, are commonly coloured with water colours, and this can only be done successfully by skilful artists so as to bear the close inspection to which such pictures are subject. This invention consists in the use of collodion as a medium for receiving dry colours on such pictures.

THE ECLIPSE OF THE 17TH INST.—We have received from Mr. W. Deane, of Richmond, Surrey, an interesting card picture of the partial eclipse of the sun on the 17th inst., taken 6h. 10m. p.m., a little before the greatest phase of contact. The crescent sun is bright against a dark looking sky, and is surrounded by singular radiations of light, assuming almost the shape of a cross. Some foreground objects loom black and heavy against the sky, and give force to the picture.

To Correspondents.

- C. C.—We have not found any injurious effect from the use of water containing traces of carbonate of lime. If present in large quantity a film of carbonate of silver is sometimes formed on the surface of the print when washing before toning. This may be removed by sponging. 2. The bath of acetate of soda and gold should be made 24 hours before use. 3. Sutton's calcio-chloride of gold has been in the market for several months, how long we are uncertain. It is to be had of Bailey and Son, of Wolverhampton.
- D. G. SUTTON.—The colour of the interior of a glass studio is somewhat a matter of taste. Any quiet agreeable neutral colour may be used. 2. From your description the negative collodion has become insensitive through age, which has caused decomposition. It is not a usual circumstance with the collodion of the maker you name. Probably he could give you some explanation. When once collodion becomes insensitive through age there is no efficient remedy. Adding a little of a bromide will sometimes effect a little improvement, however. Sometimes you may mix such a sample off with a more sensitive sample with advantage.
- E. E.—Of the two lenses you name, a half-plate and a No. 2 B of the same maker, the latter is more suitable for cards than the other. The half-plate will take excellent cards, but will require a longer room and will not be so rapid as the No. 2 B. You cannot do better than use the latter.
- D. DEAN.—We are always anxious, of course, to obtain the details of successful formulae for publication. But where there is a specific reason for not publishing we always respect any confidence reposed in us; we shall, therefore, have pleasure in receiving the information either for private use or for publication as you may decide. We think Schering's paper is prepared either with zinc white (oxide of zinc), or mineral white (sulphate of baryta).
- AN AMATEUR.—Shellac varnish is made by dissolving the resin in wood naphtha or alcohol. It may be applied with a brush. 2. We have no information as to when Mr. Keene's work on "Rapid Dry Collodion Process" will be ready. Major Russell's new edition is, we understand, in the press, and will shortly be published. We have no information as to when the English translation of Dr. Monckhoven's manual will be ready. 3. Where you send for the catalogue of any firm, enclosing stamps for postage, and do not receive a reply, we presume the matter has been overlooked, or possibly the catalogue is reprinting. 4. You may use the shellac varnish for the inside of a wooden bath. 5. The best cement for glass vessels to be used in photography is marine glue. 6. If your nitrate of silver solution has become discoloured by standing in the light, it indicates the presence of some foreign matter. Let it stand in the sun a few hours and then filter, when it will probably be all right.
- R. G.—We are glad you have found the iron intensifier so efficient; and also that you are so busy and successful. We do not know of a printer at present, but will bear the matter in mind.
- J. ANDERTON.—The difference in the colour of your negatives with the same collodion in two different baths arises doubtless from the old one containing some organic matter, whilst the other has none, and possibly too much nitric acid. It is possible also that the new one is not quite saturated with iodide of silver. A collodion richer in gun-cotton will give you a creamy film without interfering with rapidity. 2. The cause you mention readily accounts for the want of light in your glass room. 3. We do not know that either of the gentlemen you name could aid you much. You need not apologize or besitate to apply to us for advice. If you send us an addressed envelope we can send you the address of some skilled portraitist.
- P. M.—Lanc Price's formula for a negative bath differs little from that gene-

rally in use: dissolve 1 ounce of nitrate of silver in 2 ounces of distilled water, and add 4 grains of iodide of potassium dissolved in a drachm of distilled water, and shake well. Then add 14 ounces of distilled water, and filter out any precipitate which is formed. Next add alcohol 2 drachms and sulphuric ether 1 drachm; and make the solution very faintly acid with acetic acid. 2. Carbonate of lime is common chalk.

J. BURGESS.—Twelve grains of chloride of ammonium are more than are necessary to each ounce of albumen; 8 or 10 are sufficient. 2. Diluting the albumen will give a less glossy surface; it is a matter of taste as to which is best. 3. It is always best to use fresh eggs, but it entirely depends upon the state and temperature of the weather as to how long the albumen can be kept without absolute deterioration. 4. Extreme care in manipulation and practice alone will enable you to avoid air bubbles. 5. Judging from appearance, without actual trial, No. 1 is best of your samples.

JAMES DATE.—We cannot account for the discrepancy of your experience in using the acetate bath, with that of others. We find no difficulty in keeping it, nor in using it over and over. Some very first-rate photographers like it best when it has been used once or twice. The brown print appears to be scarcely toned at all. Try the lime formula.

HYPO.—Some of your prints are good, but there is in many a tendency to flatness from the presence of too much front light. There is also in some a little want of sharpness. The printing is pretty good.

F. BRIGGS.—The case you state certainly seems a preposterous and unreasonable one. It seems incredible that the accumulated residues of nine months, consisting of two gallons of thick argentiferous "mud," should only yield the value of 1s 6d. in the precious metal. But we don't see how we are to help you. If you mingle all your residues, containing fixing solutions together, bear in mind that common salt is not the material to precipitate them, but liver of sulphur. If you added hypo solutions to these residues, any chloride of silver present would be dissolved and washed away. In such case your "mud" might contain very little silver.

T. A.—The answer given to you by Mr. Crookes was based on the experience of Mr. Piazz Smyth, which is not contradicted by any other evidence that we are aware of. Mr. Glaisher's experiment has so far illustrated that there was less actinism at an altitude of three miles, but not that there was less light. We will, however, take an opportunity of submitting your letters to him. His address is, Royal Observatory, Greenwich.

MOSTON.—A considerable number of articles on photographic engraving have appeared in the PHOTOGRAPHIC NEWS. We may mention Nos. 7, 15, 38, and 40, as containing interesting articles on this subject. A mixture of bitumen and bee's-wax—the latter in small proportion—is used to resist acid.

BACUP.—There are a number of excellent and cheap photographic manuals Bland and Co.'s PRACTICAL PHOTOGRAPHY, and our ALMANAC will equip you with information. Mr. Hughes's Manual, of which a new edition is in the press, is very excellent.

E. E.—Add common salt, until all the silver is thrown down, and then reduce it as described by Mr. England in our last. Or if you do not wish to obtain metallic silver from the solution, but merely solid nitrate, evaporate by gentle heat.

H. FIEBER.—We have examined some samples from the firm you name, and found it very good, but we cannot state that it is all so.

T.—Some back numbers of the PHOTOGRAPHIC NEWS can be had, but some are out of print. 2. A nitrate bath, of 50 or 60 grains to the ounce, will give you a rich vigorous image, but unless it is very acid it is unmanageable, and apt to cause stains, &c. 3. If you tone in a diffused daylight, you do not peril the permanency of your prints, but you risk degrading the purity of the lights. 4. The only use of alcohol in the developer is to enable it to flow freely over the plate, when the bath is old—otherwise, it is better absent. 5. Old collodion baths should not be used for printing—the prints are generally poor, and do not tone well; besides, 45 grains to the ounce is not strong enough. The prints cannot be very brilliant or good.

W. W.—Our pages abound with articles on the production of transparencies for the magic-lantern, &c. We may call your attention to two numbers in our last volume, giving details, viz., 188 and 208. Albumen plates give great force and crispness, but we have seen transparencies on Tannin plates, which were scarcely inferior, whilst the trouble of preparing them is much less. If you produce transparencies by the wet process, the simplest method of changing the colour to black is to treat them first with bichloride of mercury, and, after washing, apply a weak solution of ammonia. 2. A thin, highly-albumenized paper is best for cards. See our ALMANAC, for various toning solutions, with the characteristic qualities of each.

VERAX.—A silver solution is not weakened by standing in an open vessel; sometimes, indeed, it becomes stronger, by the evaporation of the water; but the plan is a slovenly one, as the solution must become contaminated by dust, &c. The best plan is to use the silver meter from time to time to test the strength. A little colour in the printing bath does no harm, but it is better to keep it clean by adding now and then a few drops of a solution of salt, and shaking. If a print remain 10 minutes in a toning bath without any change of colour the bath must be very inert indeed. Prints should be rinsed after toning before passing into the hypo bath. The time required for fixing is generally 15 or 20 minutes.

RECENT MODIFICATIONS IN THE TANNIN PROCESS.

THE tannin process in its original simplicity rarely fails to give good results where the manipulations are conducted with reasonable care and the materials are moderately near the mark as to purity and exact formula. As modifications are introduced, difficulties begin to be felt, and it has generally happened that these difficulties have borne a somewhat definite ratio to the increase of sensitiveness gained. The more sensitive the film becomes to light, the greater the tendency to fog and other troubles—such as want of intensity, &c. These conditions are not necessarily confined to the tannin process, but appertain, in a greater or less degree, to all processes, wet or dry; and we simply note the circumstance to remark that in proportion as improvements in sensitiveness are effected, in such proportion will precision as to formula and care as to the manipulation become imperatively necessary.

The increase in the proportion of bromide, whilst it gives increased sensitiveness and softness, renders necessary more care to secure other conditions of vigour. The use of ammonia in development, whilst it shortens the exposure, demands more care to avoid fog and stains. The use of hot water in development brings about similar results. The addition of honey or gum to the tannin, whilst it has in many hands increased the sensitiveness, has in others injured the stability or keeping powers of the plates. The latter aids, the use of honey or gum, or the aid of heat in development have proved, in Major Russell's hands, of such doubtful value that he does not adopt or recommend them as integral portions of his process.

On the other hand, we may remark that the most successful rapid tannin photographs we have seen, have been obtained by one or the other of these aids. The best rapid dry-plate picture in the late Exhibition was Col. Stuart Wortley's quasi-instantaneous "Sun-set at the Island of Ischia." This was obtained on a large tannin plate with a Dallmeyer's triple lens, highly-bromized collodion, and the aid of heat in development. With the aid of honey and other modifications, Mr. England has obtained some of the best and most rapid tannin negatives we have seen. His experiments are not yet completed, and as there is some probability that he will compete for the Marsell's prize, he does not at present publish his formula; but we may state that on a recent visit to his studio, we saw a plate exposed which gave a moderately good and very soft negative, produced in a very bad light, with about double the exposure which would have been necessary for the wet process. Other negatives we saw which had been produced in a good light, that had all the delicacy and general characteristics of those obtained on wet plates.

We are at liberty to mention so much of Mr. England's operations as may be suggestive to other experimentalists. A very large proportion of bromides is used, and in some cases an equal proportion of iodides. In the case of the

plate we saw exposed, the collodion had six grains of iodide and six grains of bromide to the ounce. The plates were well washed and the preservative contained both tannin and honey, five grains of each in an ounce of water. After exposure, the film was moistened with common water: a solution of carbonate of ammonia, a grain and a half to the ounce of water was then applied, which brought out a phantom image. Next a mixture of this solution with a little pyrogallic acid was used, by which the image was fully developed; but without vigour. It was now intensified with pyro and silver in the usual way. The whole operation of development did not occupy more than four or five minutes, was effected without any fog, giving an image very like that of a wet plate, and although the glass had no preparation except grinding the edge, there was not the slightest tendency to loosening of the film manifest. We have since printed the negative and although it looks unusually thin for a dry plate it prints well.

Major Russell who has been indefatigable in establishing the conditions of success in working his process, has recently in answer to the queries of one of our correspondents, furnished us with copious and interesting details as the probable sources of certain difficulties to be met. And as the difficulties of one experimentalist are probably those of many, we shall give here a condensation of those of the correspondent in question, and then add the information with which Major Russell has so kindly favoured us.

Our Correspondent, who signs himself "Tyro Tannin," says:—

I made my collodion exactly as in Major Russell's formula. The plates were coated with a rather strong solution of gelatine put on warm. The bath was sixty grains to the ounce, saturated with bromide of potassium, and slightly acid with nitric acid (is this right?). The developer, six grains, carbonate ammonia, one grain pyrogallic acid to the ounce. In the first place, I found the film tender in the bath, and easily torn or peeled off, and when it got through the washing entire on development, in all cases ran into blisters. In one or two instances I have been able to get the picture to the proper intensity without fogginess, but it has almost always fogged over when about half-finished, although I did not keep the developing in and it always remained quite clear. On trying to finish the development, with the ordinary pyro-gallic acid and silver, having washed off the carbonate of ammonia, I found that the blisters condensed.

I have tried a few plates, from which the following appear to be the results of different ways of developing:

That newly mixed or old mixed developer, six grains ammonia, one grain pyro, are equally good and both for the picture before completion. That development in a tray of the solution has no advantages in that respect. That an advantage seems to be gained by covering the plate first with a very strong solution of carbonate of ammonia, which starts the development, and on adding a few drops of a solution of pyrogallic acid, one grain to the ounce, the development proceeds rapidly.

The process appears to be extremely good as to sensitiveness. I tried a plate with part ten seconds, and other parts twenty, thirty, and forty seconds respectively. In the ten

seconds, all the details appeared to be out, but it remained very faint. I should say that my lens is a Ross's orthoscopic, and I was working with full aperture.

I made a print from a trial plate this morning, but had not time to tone or fix it; but as it may be interesting to you to see it, I enclose it. The negative was exposed forty seconds above lens, with full aperture: this was much blistered, but the development having been completed without any silver, no spots to transmitted light were formed, although by reflected light it is much spotted.

Major Russell, in replying, first explains that in a recent communication, the object of recommending five parts of ether and three of alcohol, was to secure sufficient setting qualities in collodion made from ordinary samples of pyroxyline, as the effect of a bromide only is to retard setting. Equal parts of alcohol and ether may be used with advantage with a suitable sample of pyroxyline. The cotton we have generally used and recommended, namely, that made with equal parts of nitric acid at 1.420, and sulphuric acid at 1.840, the cotton being immersed at a temperature of 150° Fah., Major Russell finds very sensitive but deficient in setting powers when a bromide only is used. In reference to the difficulties of "Tyro Tannin," above given, we make the following extracts from the Major's communication:—

I will do my best to explain your correspondent's difficulties, but cannot be sure about their cause, as so many things may produce the same faults. I was much interested in hearing his experience as I have been working quite alone, and have had no report of my method from any one except Mr. Glover, of Liverpool, who found it succeed well, and said that the gain in sensitiveness was even greater than I said. I regard your correspondent's account and specimen to be very favourable, as the difficulties he complains of are very easily avoided, and he seems to be quite free from the only real difficulty in working with tannin—blurring and loss of distance with landscape subjects. I find that this difficulty is entirely avoided by the use of bromide alone.

With regard to the difficulties, the gelatine solution was probably too strong. I never use it now stronger than 2½ grains to the ounce: one drop of glacial acetic acid is quite enough, I find, for double this quantity. If much acid were used, and not well driven off by heat, the evil would be increased. The pyroxyline was probably of an unsuitable kind, intended for dry plates, and perhaps of such a kind as would make too thick a collodion with 5 grains to the ounce; samples vary greatly in this respect. The tannin solution, perhaps, did not contain alcohol enough to penetrate, and the film might not be long enough subjected to its action to allow it to penetrate sufficiently, but the evil evidently commenced sooner. The fogging might be caused by the bath being impure, as one kept permanently acid is sure to be; or by using strong solution of carbonate of ammonia, which is pretty sure to produce more or less fogging; or very probably by light affecting its plates while being prepared.

It is better to give a plan which will succeed well than to go deeply into the causes of failure, at least this course takes less time. Although the coating of gelatine will work well in my hands with bromized collodion and the alkaline developer, I think that the following plan is better in this case. When the glasses are cleaned make them pretty warm, and paint thinly round the edges with a 2½-grain plain solution of gelatine. It dries as fast as laid on. When cold cover the whole with a very weak solution of india-rubber, or india-rubber and amber in chloroform and benzole: all this takes but a few seconds for each plate if many are done at once. After this, in my hands, the film does not move at all throughout the whole treatment. I find it best to keep the bath solution with carbonate of silver in the bottle, and, if necessary, to acidify after pouring out for use with a very small quantity of nitric acid. If the bath has been much used in an acid state it should first be made alkaline with ammonia and well boiled, or exposed for a few days to the sun, then filtered, acidified with nitric acid, and neutralized with carbonate of silver. This way of managing the bath will, I think, be found to be by far the best yet devised.

Immerse the plate when perfectly freed from nitrate in an 8-grain solution of tannin in water, and a large proportion of alcohol, wash uniformly till oiliness disappears, and dry spontaneously. Great care must be taken not to expose the excited plate to even the most non-actinic light more than is necessary,

as bromide is very easily affected by coloured light, and fogging is often thus caused.

The best formulæ for the alkaline developer I find to be as follows:—

		No. 1.	
Carbonate of ammonia	6	grains.
Alcohol, 830	1½	oz.
Distilled water	2½	ozs.

This may be left mixed any length of time in a bottle.

		No. 2.	
Pyrogallic acid	1	grain.
Alcohol and water in the same proportion as in No. 1	2	drachms.

This should be freshly dissolved diluted from an absolute alcohol solution.

Pour on the dry plate enough of No. 1 to cover it, by tilting; two drachms is ample for a stereoscopic plate; let it remain on some minutes, at least, then pour off and mix with one-fourth its bulk of No. 2, pour on so as to sweep the plate all over on tilting, as with an iron developer on a wet plate, for the image, if sufficiently exposed, starts out at once. Pour on and off a few times quickly, and then let remain at rest. If not too much exposed it will be come sufficiently intense in an hour or two, during which it requires no attention.

If too much exposed it must be washed off quickly and intensified with pyrogallic and acid silver, but the film must be well washed between the two operations—insufficient washing may have caused some of your correspondent's troubles. On no account must more ammonia be added after the mixed developer is once on the plate, or fogging will be caused.

I find that the pyro and carbonate of ammonia, when once mixed, quickly loses force, so that if the same mixture is used in rapid succession on two or more plates, the first will always come out best.

However the development is performed, it is important to have a large proportion of alcohol in the liquid which first moistens the film to avoid risk of its becoming loose; if alcohol was not used it would account for the loosening.

Your correspondent's plan of using the carbonate of ammonia in strong solution is, I think, a very bad one, and nearly sure to produce fogging, as I said before. The pyrogallic should be added all at once—subsequent additions after a few seconds' development do no good. The pyrogallic may be used in larger amount, but I recommend that the strength of the carbonate ammonia solution be not exceeded. I hope I have given sufficient explanation to enable your correspondent to avoid his difficulties, which probably rise from a combination of causes. The plan I have described answers perfectly well in my hands, and seems quite free from difficulties.

I may add that I never recollect to have found the film tender under any circumstances when on gelatine. Although strong carbonate ammonia produces slight fogging, yet it might cause less than the proper method if the plates have been injured by light, as the strong alkaline liquid produces great intensity quickly, but makes the plate appear less exposed, that is, fails to bring out feeble impressions of light, whether made in the camera or out of it. I have no doubt that the great sensitiveness of the plates prepared with bromide alone, together with the sensitiveness of the bromide to coloured light, will cause difficulty when great care is not taken about light in the dark room.

We understand that the second edition of Major Russell's little work on the Tannin process is now in the press, and will shortly be published. It will doubtless contain much valuable information on this interesting subject.

Scientific Gossip.

NEW SOLVENT FOR SILK—IMPROVED SPECTROSCOPE.

In our former volumes we gave some notices of a process for dissolving cellulose (cotton fibre, &c.) in an ammoniacal solution of copper. Several attempts were made to utilise the solution thus obtained in photography, and indeed in our

pages will be found details of processes which, whilst tolerably successful in themselves, promised still further valuable results if the subject had been taken up by more experimentalists. Probably the great excess of ammonia which it was necessary to have in this solution, and the consequent unpleasantness of working with such a liquid under one's nose, together with the danger to other photographic operations which would be likely to arise if these fumes were allowed to escape into the photographic laboratory—all acted as reasons for preventing this path of inquiry from being followed up. Some recent researches of Mr. J. Persoz have resulted in a similar discovery of a solvent for silk, which does not touch wool or cellulose, and further trials have shown how to separate all the chemical solvent from the silk, and leave the latter in the state of pure aqueous solution. We have little doubt that this solution of silk would prove of great value in photography, and for the benefit of those who may desire to experimentalise on the subject, we will give the process employed by the discoverer to obtain such a solution. Silk rapidly dissolves in a hot concentrated solution of chloride of zinc and more slowly in a weak and cold solution. But though chloride of zinc readily dissolves silk it does not destroy the texture of wool or vegetable fibres, so that by means of this reagent the complex nature of certain tissues can now be more easily distinguished.

Thus the silk may be dissolved by chloride of zinc, and the wool destroyed by soda, so as to leave only the vegetable fibres. To different learned bodies samples of wool and silk tissues have been exhibited, a portion of which has been dipped in chloride of zinc. The silk was all dissolved out whilst the wool was left intact. The solvent employed by M. Persoz is chloride of zinc concentrated to about 60° of the areometer. This is to be boiled with excess of oxide of zinc until it becomes sensibly neutral to litmus paper. It is in this state a basic chloride; when distilled water is added to it, it does indeed become slightly turbid, but the solution has the advantage of causing no alteration in vegetable tissues which may have to be isolated in the course of the experiment. If excess of free hydrochloric acid be present it might dissolve cellulose, as this acid has been found to exercise a strong solvent power on vegetable fibre.

On contact with chloride of zinc prepared as above described the silk is converted into a gummy mass, preserving at first the form of the threads of the tissue, but changing gradually to transparent clots, and finally becoming completely dissolved. In fact the process of solution is very similar to that of dissolving gun-cotton in alcoholised ether. Chloride of zinc of the above strength gradually dissolves a considerable quantity of silk at the ordinary temperature; but under the influence of heat the solution is effected in a few instants, becoming viscous and capable of being drawn into threads like a thick syrup. It then resembles a strong solution of gum arabic. Ammonia produces in this solution, after dilution with water, a white precipitate which dissolves completely in an excess of reagent. Probably this is oxide of zinc. M. Persoz does not say if he has taken any steps to ascertain whether it contains any silk precipitated along with it. Many chemical means have been tried to separate the silk from the chloride of zinc used as a solvent; but after once being obtained in solution it resisted all attempts to separate it until the beautiful dialytic method of Professor Graham was tried. The silk solution was first diluted by pouring it into water acidulated with hydrochloric acid. Acid was used in preference to water as the latter alone would induce the precipitation of the basic chloride of zinc referred to previously. The acid prevented this. In a former experiment the solution, having been twice filtered without getting rid of its slightly opalescent appearance, was placed on the dialyser. A large quantity of chloride of zinc passed directly, and after a few hours the liquid became much more viscid. It then increased in volume and became an opaline, jelly-like starch. This jelly contained yet a little chloride of zinc which could not

be separated on account of the new physical condition of the matter. It had the insipid taste and smell of starch, whilst its chemical characteristics were dissimilar. In fact, it did not swell with caustic potash nor liquify with sulphuric acid. It was soluble in acetic acid like steeped starch, yet, if dried, it no longer dissolved in this reagent, being transformed into vitreous and brittle fragments. In succeeding experiments the formation of this kind of fibrine starch was prevented by diluting the solution with more water before submitting it to the action of the dialyser, and especially by heating it for a few minutes, which effects the removal on subsequent filtration of the matters in suspension, to which is due the opaline appearance of the liquid. With these precautions, and by means of the dialyser, all the chloride of zinc can be separated and a limpid, colourless, and tasteless liquid obtained, being, in fact, a pure, aqueous solution of silk. This by evaporation gives a gold-coloured, friable varnish. We cannot help thinking that this aqueous solution of silk would prove a most valuable vehicle for the photographic chemicals. It would, we think, be superior to albumen in many respects, and for all processes in which this liquid is now used it might be experimented upon. The expense of preparing it would be very trifling, and the trouble equally unimportant. Chloride of zinc is cheap enough, and the whole of it would be recovered for a subsequent operation by evaporating down the solution which passed through the dialyser.

A very ingenious form of spectroscope has just been completed at the suggestion of Dr. Walcott Gibbs, involving a new principle, or rather one for the first time applied to instruments of this kind. In this instrument the prism of flint glass has a refracting angle of only 37°: the rays which diverge from the slit are rendered parallel in the usual manner by an achromatic lens having the slit in its principal focus. The bundle of rays then falls upon the first surface of the prism at a perpendicular incidence, and of course makes an angle of 37° with the second surface. Under these circumstances the refraction takes place at an angle so near the limiting angle that the refracted rays emerge nearly parallel to the second surface of the prism. The amount of dispersion produced in this manner is very great, while the loss of light occasioned by reflection at the first surface in prisms of 60° placed in the position of minimum deviation is avoided. The spectrum thus produced possesses remarkable intensity, and the dark lines are seen in countless numbers and with great distinctness. The instrument in this form is sufficient for all chemical purposes, but it is so constructed as to permit the use of a second prism by which the length of the spectrum is of course greatly increased.

Though the telescopes are only 6 inches in length, with a magnifying power of about 6, the spectrum compares very advantageously with that of a large apparatus with telescopes of 18 inches focal length and $1\frac{1}{2}$ aperture, and a prism of 60°. It may here be mentioned that the centre of the second surface of the prism lies in the vertical axis of the instrument and also that in a prism of this kind the refracted rays diverge as if from a single radiant point, which is not the case with prisms of the ordinary construction, the angular dispersion being at the same time much greater.

A PLAN TO MAKE CONSERVATORIES AVAILABLE FOR PHOTOGRAPHIC PURPOSES.

It is undoubtedly desirable to have the glass studio so constructed that no sunlight can enter, for with the light from the north or north-east it is much easier work for the operator, the exposure being moderately uniform during the working hours of any ordinary day. But there is a very large class of photographers—especially that enthusiastic, untiring body of hard workers called amateurs—who are compelled to utilize various conservatories already in existence, and as the sun is blazing down upon them throughout the day,

they experience no little difficulty in securing anything like presentable results. The object of the present remarks is to describe how the difficulties were lately overcome in the fitting up of a glass house facing the S.E., trusting they may be of service to many who have no alternative but to use some place with this very undesirable aspect. The house I refer to is situated at the bottom of my garden, and is 32 feet long. It is built against the end wall, and resembles in most particulars an ordinary lean-to conservatory. The whole of the roof is glass, and there is about 9 ft. glass in the side nearly in the centre of the building. Of course I found on dull days a great deal too much diffused light in the place: the pictures taken being flat and unsatisfactory; whilst on bright days I had a blaze of sunshine in the place and could do nothing.

I first tried blinds all over the roof and a black canopy over the sitter. This, however, answered indifferently, for while on dull days I could, by pulling up one of the blinds in the middle, let in a little pure light, and so got good results, yet when the sun shone and all the blinds were down, I had a grey diffused light and could get no roundness. I now determined to shut out all the light except about 12 ft. in the centre; and accordingly papered the glass with thick dark blue paper such as is used for wrapping up goods by chemists. I covered all the glass at each end with this paper, and half-way down the sky-lights in the centre. The following diagram will best illustrate what I mean.

The shaded parts show the amount of skylight covered by paper. It will be seen that a very small portion of the sky-light is left uncovered.

I now had made two light frames, and covered them with very thin white tissue paper. These frames were half the length of the sky-lights left white in the diagram, and were made to fit exactly into the recesses formed by the bars supporting the roof. They were now placed in position, and held there by a few nails lightly driven. Three pieces of wood planed smooth, and about an inch each way broader than the bars supporting the sky-lights were now screwed on the bars. The centre one forming a double groove, thus:—

The two end pieces, of course, were not so broad, as only single grooves were needed. As soon as the three pieces were in position the nails were pulled out. A cord was now fastened to the top end of the frame and carried through a pulley at the top and a corresponding one at the bottom. By this means in dull weather the transparent frames were pulled up to the top under the blue paper, but in bright weather they were let down and effectually shut out the sun, but admitted a large amount of pure bright light. The tissue paper, when in its place, looks like ground glass, but lets in, I think, more light. It is quite out of the way, and therefore not likely to get torn. It is somewhat difficult to get the frames in position without tearing the paper, but a little care will get over the difficulty.

It would be possible to do without these frames if the glass house be tolerably high, say 9 ft. at side. The plan to

be adopted in this case would be to go over the portions of glass not covered by blue paper, with paper varnish, adding a little wax dissolved in hot turpentine to it. Now take the tissue paper in broad strips and carefully lay them on the glass and rub them down, taking care not to get air-bubbles. This is somewhat a difficult operation, but to be overcome with care. When all the paper is put on, go over it with the same varnish, but be careful not to put too much on. When dry it will be found very transparent but will let in no direct sunlight.

The side light is of course easily managed. White blinds either to slide or roll will completely shut out the sun at will.

I find, now that I have perfected the arrangements here described, that the light is very nicely managed, and that I get just the effect I desire. The details of the pupil and iris are well made out in the eyes of my sitters: the nose well defined, and from the wall a nice amount of reflection is thrown into the shadow side of the face. The light falling on the sitter is very pure and brilliant even on moderately dull days while sunshine now causes me no trouble, and the sitter is not inconvenienced by it. The exposure for my pictures is very short, being about an average of 10 seconds, with No. 2 stop in one of Squire's improved Shepherd *carte de visite* lenses. The negatives are frequently so round and dense that they need no further intensification.

I have forwarded a print from one of the negatives taken since the alteration, and shall be glad of your opinion thereon.

FORMIC ACID IN THE DEVELOPER.

BY K. STAUNTON.

On reading an article in your columns of the 15th inst., by H. G. Cooper, Jun., on the introduction of "Formic Acid in the Developer," I am induced to offer the formula from which I obtain the best results, as being, I think, more simple, and, consequently, entailing less trouble and loss of time on the operator.

I have for some time adopted this formula with unvarying success, and providing the chemicals are *good*, feel convinced it is to be relied upon.

It is of the first importance that the formic acid be *pure*, its not being so is, I anticipate, the cause of many experimentalists failing, and thus aiding to hinder the general adoption of a process which undoubtedly gives the nearest approach to instantaneous photography yet obtained in our glass houses, besides showing better results than either pyrogallie acid with acetic acid, or sulphate of iron developers. One striking advantage which it possesses over protosulphate of iron is that in the case of pushing the development too far it does not destroy the half tones, but simply reduces the vigour of the negative. When the proper exposure has been given and the manipulation carefully carried out, the negative is soft and harmonious, delicate in detail, and withal, vigorous and clean.

A second and yet more important consideration in its favour is that it requires *no intensifying* save under quite exceptional circumstances.

With an ordinary light I take negatives with very excellent results in one and a half seconds, and in no case do I allow more than *four* seconds exposure, which is *less* than one-fifth under what I give in the same glass room for sulphate of iron development. With this process I was enabled to take a very fair negative of a sick infant in an ordinary sitting room with a *carte de visite* lens at 3 o'clock in the afternoon in 10 seconds.

I have used three samples of collodions, all of which I found equally good, subject to a slight variation in the exposure, viz., Hockin's instantaneous, Thomas's negative and cadmium mixed, and Ponting's.

The bath should be a 30-grain of decided acidity (nitric acid).

	Formula.		
Pyrogallic acid	20 grains
Formic acid	2 drachms
Distilled water	9½ ounces
Alcohol	quant. suff.

On applying the developer the image instantly appears, after which the film gradually darkens, and the image becomes more indistinct. Keep the liquid gently flowing, watching carefully for the precise moment when the image has attained sufficient intensity (which by a little practice may be easily ascertained), then pour off, wash rapidly, and fix with cyanide.

If intensifying prove requisite the ordinary pyrogallic acid, and a 20-grain solution of silver should be employed; but during the past two months I have had three instances only in which I found it desirable to intensify.

If the chemicals be pure, the exposure good, and the manipulation satisfactorily conducted, the high lights will show a thick creamy appearance by reflected light, the half tones being very delicate and pure, and the shadows clean and brilliant.

Failures in experiments often result from the formic acid being too strong, which reducing the silver leaves a greyish-white deposit on the shadows; or, in the case of an impure sample, the image fails to develop beyond a certain point, and by transmitted light shows little more than a cloudy and irregular film.

There are several points of advantage in the use of formic acid besides those tending to the perfection of the art, and which are very important to houses where the business is large, and the economy of time valuable, for the simplicity of the manipulation renders the process extremely rapid. And again, to photographers who are unable to command an abundant supply of water, the film not requiring nearly so much washing between the use of the developer and the fixing agent, as in protosulphate of iron, or pyrogallic with acetic acid development. A third consideration being the rapidity with which negatives by this process print.

THE DIORAMA AND PHOTOGRAPHY.

IN the PHOTOGRAPHIC NEWS for December 19th, 1862, appeared a detailed account, by Dr. Taylor of Glasgow, of certain dioramic effects which he had succeeded in producing on photographic pictures, with a description of the apparatus by which these results were obtained. In this account it was stated that the chief defect—we should have said the only defect—of those pictures, lay in the fact that they could be viewed by only a very limited number of spectators at a time. Since then, Dr. Taylor has been patiently continuing his investigations in order to remove, if possible, this inconvenience. On a recent evening the members of Council of the Glasgow Photographic Association met with a few friends, one of whom was the writer of the present notice, at the residence of Dr. Taylor, for the purpose of witnessing the complete success which has attended his endeavours. In describing the results we shall say little of the technical details by which these have been achieved, already made familiar to our readers by the former account of the dioramic process, but shall briefly notice the startling and beautiful atmospheric changes which by these arrangements are produced on photographic pictures, and their suitability for representation to large assemblies, merely premising that the cosmoramic boxes and magnifying lenses are now altogether omitted, and the picture presented directly before the audience behind a species of proscenium as in the common diorama. In this way the number of spectators may be limited only by the size of the room. In the present instance the picture was seen from a distance of forty feet. The subject of the experiments to which we now refer was a view of the Broomielaw, or harbour of Glasgow, measuring 40 by 32 inches, taken by Mr. Kibble of that city, and generously presented by him for the purpose. Being an ordinary paper

photograph, it was necessarily not transparent, except where the paper by scraping had been intentionally thinned in order to show particular effects of light. One or two slight innovations had also been introduced into the composition of the picture, not to interfere with the genuineness of the photograph, but merely to show the various results to be obtained by the process. Indeed, the first view presented, that of the harbour in broad daylight, was sufficiently common place to show that the subsequent marvellous arrangements which were wrought upon it were solely the result of Dr. Taylor's combinations. On the right stood irregular blocks of tall buildings fronting the river, interspersed with one or two chimneys, which a little manipulation had transformed into turrets; on the left lay the long line of harbour-sheds, surmounted by the masts and sails of the vessels, while in front the spacious causeway street receded in narrowing perspective until lost in that point to which the lines of houses, sheds, and masts converged. So far, the picture was little beyond that of a simple photograph, taken under ordinary circumstances, and in ordinary light, except that every object seemed to possess a perfect stereoscopic fulness and rotundity, and that there was a breeziness and fluttering motion of the sky which gave to the picture an atmospheric distance and a reality altogether unattainable by either painting or photograph, *per se*. This effect was greatly heightened when the drifting clouds cleared away, and the sun burst forth in full splendour—seemingly at a distance far beyond that of the most remote part of the horizon, while at the same time the street seemed to fill with figures of every size and appearance. But in course of time a slight tinge of the coming sunset stole along the front of the houses, the reflection from the sky overhead became less brilliant, while a more positive light was seen to grow in the west, intensifying itself as the clouds gathered and thickened around it, until along the street came a full flood of glory, striking on the windows of the buildings, enkindling the masts of the ships, and even fluttering down upon the orange-tinted causeway. But apparently the wind is still blowing, the afternoon is wearing on, for now across the western horizon come broken masses of flying clouds, orange and crimson and tawny red, until the motion somewhat subsides, and then a blaze of purest rose-colour rises in the west, suffusing the whole breadth of the picture with its wondrous richness and brilliancy. Anything more exquisitely soft and beautiful than this wealth of colour it were hardly possible to imagine; in fact, language falls stone-dead before this triumph of art. Here having reached the very perfection of a summer evening, the sun again shone forth with its setting hues of crimson and gold, and then sunk in the thick folds of cloud.

It has often been said that though it were possible to form a rose of indestructible material, and to scent this rose with the most natural of perfumes, we should not care for it so much as for a real living rose, simply because the latter has a subtle spirit of evanescence which we know is hastening its decay even as we look. This may possibly be the reason why the most perfectly natural of pictures looks so hard and formal and definite when compared to a landscape out of doors; for even in Turner's pictures—which perhaps possess more business and life than those of any other artist—one still must see that though the ruin is falling, it never falls, that though the wind is blowing, there is no prospect of sunny weather behind, that though the hare is scampering in front of the railway-engine, the distance between them is neither increased nor diminished. But in those pictures of which we now speak the most scrupulous fidelity of the photograph may be combined with colour more brilliant than that of the brightest painting, and with the very life and motion and change of nature herself; while the effect may remain stationary or be changed at the will of the illuminator.

Again, the clouds are in motion, by almost imperceptible degrees the houses and masts grow a rich dark purple, while the sky deepens in its fire and becomes striped with bands of every hue and shade. The combinations of colour which

may thus be presented are simply endless; while the brightest of them—those which would look raw and glaring in a picture—are mellowed and blended together with an indescribable softness and transparency. By-and-by, as the light in the west becomes less intense, the gas-light of the shops appears in the darkness, falling with its yellow radiance on the pavement, and lending a soft golden mist to the obscurity of the street; while above, as the sky becomes still darker, a few stars are seen to twinkle forth from over the roofs of the houses.

At this point, as if by magic, there appears in the street a tent, lit inside by a large fire, in front of which several dark figures are standing. This, the spectators were told, is done by an adaptation of the same principle by which the "ghost" was afterwards exhibited. The tent and figures again fade into the darkness, and in their stead come one or two coffee-stands placed along the street with figures as if regaling themselves beneath the glare of the lamps. And now these again are absorbed, and we have a moonlight scene, with the clouds parting and breaking up to allow the silvery radiance to strike athwart the houses and masts as the sunset had done during the afternoon. Nor is it merely a moonlight effect, we have a positive moon, encircled by attendant clouds that reflect her lustre in a thousand different tints. Suddenly, however, thick clouds of smoke are driven across the sky, obscuring the moonlight, and reducing the picture to utter blackness; behind the houses rises a pale red light, growing in intensity until it springs up a clear jet of flame against the dark sky. A building is on fire, and the blaze widens and brightens, then pales and sinks down into thick volumes of smoke, and again the stars come forth. Finally, across the tallest buildings flutters an indication of the coming dawn in a faint tinge of pink—growing from pink to red, from red to gold, and from gold to white, with the ships, and the streets, and the houses once more seen in the quiet light of morning, and the figures, &c., of the night altogether vanished from the scene. It will at once be evident that to produce these varied effects, the operator, besides being an excellent photographer, must have considerable artistic knowledge, and be possessed of very great manipulative skill. The unwearied diligence and well tried knowledge of Dr. Taylor have triumphed over the difficulties which lay in his way; and it is not to be supposed that these results may at once be obtained by any man who makes for himself the mechanical apparatus by which Dr. Taylor has succeeded. If exhibitions of such pictures become popular, as they have every chance to do, it will be necessary that they should not be entrusted to mere showmen, but be regulated by men of personal ingenuity, whose business will be to suggest improvements and to correct what little flaws must necessarily be found in new appliances of the kind. In the meantime, what remains to be done is chiefly the procuring of photographic apparatus competent to enlarge pictures sufficiently to be exhibited in large halls; and as the difficulties which have hitherto existed in this department are merely mechanical, we doubt not that they will soon be obviated. And we can safely prognosticate that when enlarged photographs such as the one exhibited, are procured from localities of greatest historical and scenic interest, such as Egypt, Syria, Italy, or India, and when appropriate figures, and ever-changing effects are introduced into them in the manner that is now shown to be possible, an exhibition at once the most truthful, the most instructive and the most interesting that has ever yet appeared will be presented to the world.

After the removal of the dioramic picture, at the request of several of the gentlemen present, Dr. Taylor showed the apparition of a phantom, or "ghost," in a manner similar to that which is now attracting attention in London. He stated that he had never seen the latter exhibition, but from the accounts published he was of opinion that the means used to produce the illusion must be the same as those described by him in the photographic journals of last year, and exhibited to many persons eighteen months ago.

Accordingly, a table having been placed in the position formerly occupied by the dioramic picture, and a person having been seated at it, as if reading and regaling himself at supper; suddenly there appeared in the air, close to the table, a spectre as of a human figure wrapped in the dress of the dead and gazing intently on the person in the chair. The latter in horror started back, then flew forwards as if to grasp the apparently solid and real corpse, but the hands passed through only empty space, still the apparition persisted, and only signified its feelings by the glare and wild rolling of the eye-balls. This motion of the eyes, after a little, again subsided into a glassy stillness, which had a sufficiently horrible and ghastly effect. The person again made a grasp at the phantom, but in an instant it vanished from sight in the spot in which it had appeared.

DRY COLLODION.

M. LIESEGANG ON MR. KEENE'S PROCESS.

We have frequently requested information on a dry collodion process which would furnish good negatives in the glass room. Mr. Keene's process has given us good results in this particular; the plates prepared, according to his formula only require an exposure in the camera corresponding to double the time necessary for wet plates. Moreover, the process is easy to perform; the negatives develop with remarkable purity.

The method we have followed is as follows. The collodion is composed of—

Alcohol at 40°	10	parts
Rectified ether	100	"
Pyroxyline	2½	"
Iodide of cadmium	2	"
Bromide of cadmium	1½	"

It must not be employed too fresh. The sensitizing bath must contain no nitric acid, only sufficient acetic acid to render the proof clear. To make the solution, dissolve 3 parts of tannin in 50 parts of water; and, on the other hand, 50 parts of gum arabic in 150 parts of distilled water. Filter the first solution, and then add to it the solution of gum; and to the mixture add 3 or 4 drops of formic acid, which serves to give greater rapidity to the plates. If the mixture is not clear, it must be filtered through cotton.

Developer.—That of Major Russell is the best.

No. 1.—Pyrogallic acid	20	parts
Alcohol	100	"
Ether	5	"
No. 2.—Nitrate of silver	2	parts
Citric acid	4	"
Distilled water	100	"

Manipulation.—The plate is prepared in the usual manner, only it is left half as long again in the silver bath than with ordinary collodion, because our collodion contains much bromide, which does not decompose so quickly as the iodides. When sensitized, the plate is left to drain for a few seconds, and the preservative solution is poured on to the plate in quantity sufficient to cover it well. It is left on the plate for a few seconds, then drained off: a fresh quantity of the solution is poured on and off twice more. The last portion will serve for the plate, but it must not be mixed with the fresh solution. After being drained, a little distilled water is poured on to the plate to mix with the preservative solution. In cold weather, warm water must be employed. The plate is next well washed in distilled water and dried.

To develop the picture, the plate must be immersed for two minutes in a dish containing distilled water to moisten the collodion film; it is developed in the usual manner with a mixture of one drachm of distilled water, six to eight drops of the developer No. 1, and three to four drops of No. 2. This mixture is made only as wanted for use.

Before preparation the plates must be carefully cleaned, and covered with a filtered solution of caoutchouc in benzine. —*Le Moniteur de la Photographie.*

COLLODION: WET OR DRY.*

BY M. L'ABBE DESPRATZ.

If, in making use of a sensitizing bath, made old naturally or artificially, we must confine ourselves to the ordinary mode of development—the employment of citric or tartaric acids is altogether impracticable. For the plate, still moist upon its removal from the camera, being covered with all possible care with the developing solution, composed of pyrogallic acid and citric or tartaric acid, no image will appear: we only see here and there at first some grey veins, which gradually darken, and irregularly marble the plate, without any regular production of the image taking place. How does this happen? The silver is reduced—that is evident; but that occurs only in places, and only where the developer has, by its mass, been able to surmount the repulsion which the silver bath opposed to it. This repulsion is enormous. The impressed film, beside free alcohol and ether, contains two fluids which mix with the developing solution with difficulty—dry in its nature, if we may so express it, while, on the contrary, the sensitizing solution is greasy. In a word, and to speak more precisely, all the difficulty arises from a defect of reciprocal affinity, which disappears or even changes into a real affinity capable of promoting the mixture, which is then immediately effected. The inconvenience we here encounter is then absolutely identical with that which we have described in the development with concentrated sulphate of iron acting upon an old bath, and therefore we should have recourse to the same mode of operating. We may be permitted to repeat it in this place, with some modifications.

The plate must first be washed on removal from the camera, until it loses its greasy aspect in the washing water. We then submit it, during a minute, to a new silver bath, strength 2 per cent. This bath must be pure; that is to say, contain neither acid, nor alcohol, nor ether; it should, in a word, consist of neutral nitrate of silver dissolved in rain or distilled water. Under these conditions, this bath will no longer exhibit any repulsion for the developing solution with citric or tartaric acid, &c., and we have now only to facilitate their mixture. To this end, the plate, on its removal from the nitrate bath of 2 per cent., must be slightly drained: it is then placed on a tripod fixed at a level, and raised at one corner, the developing solution is poured on at the upper corner of the plate, and by turning the plate in every direction facilitate its diffusion all over the surface. In the course of a few seconds the mixture is effected, or nearly so; to complete it thoroughly, it is drained into a glass measure, and solution again poured over the plate. This operation is rapidly repeated until the picture becomes visible. A complete repose is then permitted, and we wait until the details are sufficiently apparent. We can afterwards add some drops of the silver solution of 2 per cent. strength, and then the strengthening of the image may be carried as far as desired.

A word now upon the mode of developing most commonly adopted—that is to say, upon the employment of pyrogallic acid mixed with crystallisable acetic acid. The preference constantly given to this mode since it was first pointed out by M. Regnault, is in no way surprising. Its efficacy is, in fact, indisputable, and besides that the manipulation presents no serious difficulty, it is completed with a promptitude that is invaluable. Nevertheless, if we desire all possible advantage from it, there are some delicate precautions to be taken which should not be neglected.

Let us remark in the first place, that the method we have described for citric or tartaric acid, is not wholly applicable to it, as we shall comprehend immediately. By previously covering the plate with the nitrate solution of 2 per cent. and with fresh alcohol, and afterwards developing with pyrogallic acid mixed with acetic acid, the sensitive film exhibits a

very great repulsion for the developing solution, to which the acetic acid gives a consistence somewhat greasy. The mixture of the developer and the nitrate of silver is therefore effected with a certain difficulty. With the ordinary bath containing a strong proportion of alcohol, the difficulty is not so great, but yet it still exists; in either case it is easy to surmount it, as follows. The developing solution being poured upon the plate as uniformly as possible, commencing at one corner, it is immediately poured off at the opposite corner into a test glass, and without waiting for the appearance of the picture, it is poured upon the plate, then back again into the test glass. When the image begins to come out well in consequence of the reaction of the developer upon the sensitizer, we keep the solution on the plate, turning it in various ways so as to keep the liquid in constant motion over the whole surface, and render its action uniform. When the certainty of this equality of action is apparent, we place the plate level on the tripod, and allow the proof time to finish itself. Often, and most frequently, strengthening is not only useless but injurious. Still if it be considered necessary, it must be effected only when we are certain that the action of the developer is exhausted.

We must not lose sight of the fact that strengthening the image is a very delicate affair. It often happens that we, in this way, obtain very intense blacks, which most frequently yield positives with excessive contrast, and in which the half-tones are more or less deficient. When such is the effect of strengthening, we must conclude that it has been exaggerated, or, as is usually the fact, that the exposure was not sufficiently long.

In concluding, it will doubtless be useful to give the proportions we prefer in a developing solution. They are the same as those given in the excellent treatise on *Photographic Chemistry* by MM. Barreswil and Davanne. For the developer with citric acid, the following is the formula of M. Gaillard:

Water	250	parts
Pyrogallic acid	1	part
Citric acid	1	"

We have adopted the same proportions with tartaric acid, and they seem very suitable. As to the developer with acetic acid, we believe it advantageous to increase the proportion of acetic acid and decrease that of pyrogallic relatively. We prefer the following proportions:

Water	250	parts
Pyrogallic acid	0.5	"
Acetic acid	15	"

If the sensitizing bath contains much alcohol and ether, the proportion of acetic acid may be still further increased. The development will be slower, it is true, but it will be more regular and delicate. Only we must take scrupulous care to effect the complete mixture of the developer with the free nitrate of silver on the plate.—*Le Moniteur de la Photographie.*

ON PHOTOGRAPHY AS A FINE ART.

BY W. D. CLARK.*

MUCH has been said of late about the claims of photography to be considered one of the Fine Arts. I cannot help thinking that if the discussion had been conducted with a less display of temper, photographers would have arrived at a clearer estimate of the position due to their art. The claim put forward implies that photography should be held as in some degree equal to the art of painting. But, surely, photography, looked upon as an intellectual pursuit, is far inferior to that noble art. To begin with, it is entirely devoid of the beauty and expression to be got from the use of colour. Imagine artists obliged to produce all their pictures in the single grave colour that the photographer commands, and we at once see how much their art would sink in public estimation.

But this is not the chief disadvantage under which pho-

* Concluded from page 133.

* Read before the Photographic Society of Scotland, May 12.

tography labours. The greatest power the painter possesses is that of giving expression to the human face, or in conveying his own feelings and emotions whilst depicting natural scenery. The photographer cannot do that. He can only copy the expression of his sitter or the landscape before him. He has no power, whatever, of telling a story or appealing to the feelings through the expression of the human face; and this, surely, is the most important point in all high art.* All the photographer can do is to copy his model, and get an agreeable arrangement of lines and light and shadow. Beyond that he is helpless. Wilkie constantly used the model in producing his pictures; but suppose he had simply arranged them in the most agreeable way he could, and made as close a copy of them as his great skill in painting will allow, how small would have been the value of his "Rent Day," or his "Distraint for Rent," and how small the effect they would have produced on the public! No fence would have been needed to prevent injury arising from the visitors crowding round these works at the Exhibition.

Mr. Rejlander's "Two Ways of Life," shown at the Art-Treasures Exhibition in 1857, is, perhaps, the most elaborate attempt yet made to produce a picture by means of photography. The first impression, on looking at it, was wonder at the ingenuity of the author who had produced so elaborate a work with such imperfect means; the second was wonder at what it all meant. The meaning has been explained to us by Mr. Rejlander, but I question if any one could have found it out for himself. If it was unintelligible, it must have been a failure. So with all other attempts I have seen of the same kind; they fail from the total absence of expression in the figures that should tell the story.

The world generally estimates the value of any pursuit in proportion to the intellectual effort employed in it. High scholarship, eminence in science, law, or medicine, are all honoured on account of difficulty in their attainment. We all know how difficult an art painting is, from the small number of those who succeed in it. But there is no great difficulty in producing a first-rate photograph.† A person of average ability, and who can use his hands neatly, if properly taught, could probably become a good photographer in three months. It takes many years' thought and toil before an artist becomes master of his profession. Few men attain this much before middle life. To turn out a first-rate carte de visite is a comparatively easy matter. To paint a portrait as well as Sir John Watson Gordon is a very difficult thing.

What photographer could ever hope to make the most distant approach to the noble picture by Leys, now in the Scottish Academy's Exhibition? Or, to take a much simpler example, was there ever a single figure produced by photography equal in beauty to that of "Antonio," by John Phillip, in the same Exhibition? Again, M'Culloch's picture of "Bothwell Castle" is as true to the locality as any photograph of the same spot could be; but no photograph has yet produced such an exquisite representation of trees, or such a thorough feeling of sunshine, as there is in that picture.

In figure-subjects photography can only copy what the photographer has arranged; it cannot invent. It can reach the excellence of colourless tableaux vivantes—nothing more. To compete with painting is beyond its range; it can never rival that exquisite art.

In landscape subjects the photographer has, to a limited extent, the power of giving *expression* by developing his plate to a certain point, and bringing out some parts more than others, as well as by skillful printing; but this power is within very narrow bounds indeed. The finest photographic landscape, however beautiful in detail, is, in point of *feeling and expression*, greatly below the works of a great landscape-painter.

The imperfections of the lens, especially the small angle it includes, alone place the photographer at a great disadvantage. I am sure that every genuine photographer has felt, on looking at a noble landscape, how little he could do compared with an able painter.

In my own library, David Robert's volumes on the Holy Land and Egypt lay side by side with Frith's beautiful photographs of the same countries. I have often observed how much greater interest friends take in looking over the painter's work

than the photographer's. This is especially the case, I notice, with persons familiar with the countries illustrated.

Even in this instance the comparison is not a fair one for painting, as the original drawings have been translated by the lithographer.

But there certainly is such a thing as *photographic art*, and a very beautiful art it is, and fitted to do wondrous things; and photographers might well be contented to remain within its legitimate bounds. It is by cultivating it that reputation is to be gained, and not by endeavouring to trench on the domains of painting. If the public does not respect the pursuit of this art, depend upon it photographers have themselves to blame. Let them do justice to their own very beautiful art, which is so well fitted to add to the enjoyment of the world, and the public will do justice to them; and then they need not feel vexed even if some future Royal Commissioners declare that their productions must not be classed with pictures in some future International Exhibition.

The irritability exhibited by photographers whilst urging the claim of their art to be included amongst the fine arts, probably shows a lingering suspicion that their cause is not a very strong one.

The extent of the periodical literature devoted to photography is remarkable, and is evidence of the great number of people that take an interest in the subject; yet it probably has not done much to raise the character of the art. These journals profess to include both science and art; but certainly a knowledge of chemistry does not seem to be requisite in many of those contributors who write on photographic processes, and the bad taste displayed by their conductors is sometimes deplorable. An instance of this recently struck me very much. Mr. Mudd wrote to the *British Journal of Photography*, that a person, at a soirée of a Photographic Society in Glasgow, had, as reported in that journal, repeated as his own a little story of harmless humour, that Mr. Mudd had written for another photographic paper some couple of years ago. Instead of simply inserting the letter, there was put at the head of it, in capital letters, "As clear as Mud." This was, probably, intended by the editor for *wit*. To me, it seems to be the grossest impudence. It was, however, too good a thing in the eye of the offending party to be printed only once, so he repeats the buffoonery in his answer.

The editor may not know, as I do, how genial and worthy a person Mr. Mudd is, how anxious and ready he is to communicate to others the knowledge he has of his art, how good a social position he holds; but he *does* know that he is one of the best photographers in this country, and, as such, no liberty of this nature should be taken with him in a journal devoted to photography. I certainly can have no faith in the opinion on any matter of *taste* of a person who displays such an entire absence of it as this editor does in this case, nor do I think he can have much love for the art, when he takes such a liberty with one of its most successful practitioners.

If photography cannot rival painting, it can, I think, be of great use to the artist. A painter of landscape must paint a great deal on the spot; but the amount of materials collected in this way can be comparatively small, especially in such a climate as ours. Photography may be of the greatest value in supplementing his studies from nature. For bits of foreground, rocks, weeds, trees, boats, and for giving the texture of such things as the trunks of trees, it is of the greatest use. A collection of studies of trees of various kinds, showing the general forms and the ramifications of the trunks and branches, could easily be made by photography so complete that the longest lifetime, and the greatest industry, would be unequal to produce with the brush. It is almost impossible to sketch clouds with sufficient rapidity; and certainly no sketch can be so true to nature as the remarkable photographs of skies done by Mr. Breese, of Birmingham. They may be studied by the artist like Nature herself.

If it be a mistake for the photographer to attempt to rival the artist in producing pictures, I think it quite as great a mistake for the painter to try to equal the photographer in his peculiar province. No amount of care and finish will enable the artist to get the exquisite detail that a photographer can obtain in a rocky and weedy bank, for instance. The latter, in an hour's work, would get a more perfect and complete copy of the bank than the artist could with a whole summer's painting. So far as mere copying of little bits goes, the photographer is as superior in detail and finish as the painter is to him in feeling and expression, when Nature is depicted as a whole.

Pictures are sometimes seen in exhibitions that appear

* Mr. Clark here makes a common mistake, in confounding "high art" with "fine art." No claim has ever been made for photography as "high art."—Ed.

† How is it then that there are so few first-rate photographers?—Ed.

painted to rival the photograph in its own walk, but they are cold and unsatisfactory.

Photography is obviously doing good service to painting, by educating the public eye to the beauty of simply an accurate copy of nature. A picture to please now must have the forms of trees, rocks, mountains, and clouds given with truth, and with neither the slovenliness nor the exaggeration that would formerly pass muster.

The forms of rocks and mountains, as drawn by Turner, are sometimes perfectly ludicrous. Ruskin would have us believe in Turner as we would in a prophet. I have surprised some of his worshippers by showing them prints from Turner and photographs from the same point of view.

If I have ever sufficient leisure, I intend to illustrate the "untruthfulness of Turner" by a series of photographs contrasted with his prints.

I suspect that pre-Raffaeltism owes much to photography, or may even possibly spring from it, though its disciples would not willingly admit as much. Post-photography might probably more accurately describe this style of art than pre-Raffaeltism.

PHOTOGRAPHIC PIRACY.

On Friday last, at Marylebone Police Court, Thomas Wilson, stationer, &c., of 90, High-street, St. John's Wood, was summoned for "that he did on the 12th of May wrongfully sell divers repetitions, copies, and imitations of a photograph of eminent persons, about 500 in number, of which Frederick Holland Mare is the registered author and proprietor, under the 25th and 26th Victoria, cap. 68, contrary to the statute," &c.

Defendant having pleaded not guilty,

Mr. Besley, barrister, said that he appeared on behalf of Mr. Mare, a photographer, of Grafton Street, Dublin, of whom Messrs. Ashford, of Newgate Street, are his London agents. An assistant of Mr. Ashford's, on the 5th inst., entered defendant's shop, and purchased two copies of "Eminent Persons," which were piracies from the original. A letter was then sent to the defendant on the subject, cautioning him not to sell any more of them, as by so doing he was laying himself open to a prosecution under the Copyright Act, and called upon him to make some moderate compensation, give an ample apology, and promise not to deal in any more of the spurious copies, and also to give the name of the parties from whom he had the copies.

Defendant: That letter was not sent to me.

Mr. Besley: It must have been received, or else, by the ordinary process of the Post-office business, it would have been returned. However, on the 12th of May, the same person in Mr. Ashford's employ again went to Mr. Wilson's shop and purchased two other copies; and after this Mr. Bird, the solicitor by whom I am instructed, wrote a second letter to the defendant, telling him that he was infringing the copyright of the "Eminent Persons" published by Mr. Mare, of Dublin. Of this no notice was taken. Mr. Ashford was selling the print at the rate of 70 to 100 dozen per day, and of course it must be a very valuable source of profit to Mr. Mare. Proceedings were in process against a person of the name of Ordish, who is the party most to blame, he being the person who is getting up these copies from the original. If his worship would look at the original and the copy through the magnifying glass, he would find that there was a defect in the letter "y" at the foot of the picture, clearly showing that they both could not have been from the same plate. He must say in justice to the complainant that he could not be considered as the most culpable person, but the printer, against whom proceedings were being taken. The defence he has set up, however, is not altogether a very creditable one, for he sets forth that he had purchased them from Mr. Bowling, of Cheapside. Mr. Bowling was there, and would tell his worship that he had only supplied the defendant with six copies of the originals, he (Mr. Bowling) having obtained them from Messrs. Ashford, of Newgate Street. It must appear to his worship as conclusive of the defendant's infringement of the law when he (the learned gentleman) pointed out to him that all copies supplied by Messrs. Ashford bore on the back "Ashford, Brothers, 76, Newgate Street," whilst on those bought at defendant's shop there was no name or address.

Evidence in corroboration of this statement having been adduced,

Mr. Besley, in conclusion, said their object was not to press for punishment, but only that a nominal fine should be imposed, to let the trade know that, though they were not the actual printers and publishers of pirated copies, they had no right to sell them.

Mr. Yardley inflicted a fine of 1s. and costs.

Proceedings of Societies.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

The closing meeting before the summer recess was held on the evening of Wednesday, May 20th; Mr. G. Shadbolt in the chair.

The minutes of a previous meeting were read and confirmed.

Mr. G. WHARTON SIMPSON exhibited a couple of prints by Mr. Pouncey's new process, produced in printing ink, direct from the negative, with satisfactory rendering of half-tone. A conversation on the subject followed. The chairman expressed his conviction that a decided advance had been made. Mr. Simpson explained that the process was patented; but, so far as he knew the method, it consisted in coating paper with a preparation of printing ink and a sensitive agent, such as bichromate of potash. This was exposed to the light under a negative. After the proper exposure the print was placed in a solvent of the printing ink, which removed all the parts not acted upon by light.

Mr. SIMPSON also showed a series of interiors taken by Mr. Jabez Hughes, with Dallmeyer's No. 1 triple lens. Some of these consisted of the bridal chambers of the Prince and Princess of Wales, at Osborne, taken on plates ten inches square, showing a large portion of three sides of a room with every object admirably defined, the pictures being very brilliant and with great relief. The lens used, having an equivalent focus of a fraction under eight inches, the pictures included an angle on the base line of about sixty-four degrees, and on the diagonal of nearly eighty degrees. A beautiful interior of St. Mary's Church, at Ryde, on a 10x8 plate, with the same lens, was also much admired.

Mr. SIMPSON also showed an enlarged print by Mr. Stewart, with his new solar camera, printed out, on albumenized paper, in an hour. Also, some very fine specimens on a new sample of enamelled paper, of which Messrs. Harvey, Reynolds, and Fowler are the agents.

Mr. COLLIS exhibited a series of fine views in Wales, taken with Ross's 10x8 triple lens, on 10x12 plates. Also, some with the lens of 8.4 focus, and some with the lens of 9.4 focus, including an angle of 60° degrees on the base line and 66° on the diagonal. These were very much admired.

Mr. FOXLEE exhibited a small camera designed by himself and made by Mr. Hare, for the purpose of taking fifteen "postage-stamp" portraits on one plate. There were five small double combination lenses in a row, and by two repeat movements three rows of images were produced in succession.

The CHAIRMAN exhibited some fine stereoscopic negatives and prints by Dr. Kemp's new dry process.

Mr. MAINWARING exhibited some prints fixed by different agents. Since listening to the paper on fixing by the sulphocyanides at the last meeting he had tried some experiments. He had tried a saturated solution of common salt which he thought answered. He had tried cyanide which destroyed the prints. He had tried a mixture of cyanide and hypo, 1 grain of the former and 4 drachms of the latter in 12 ounces of water, and this appeared to him to fix as satisfactorily as a strong solution of hypo.

The CHAIRMAN referred to early fixing experiments with common salt, bromide of potassium, &c. The real difficulty with any agent which formed an insoluble salt of silver was to get rid of the final traces of it from the print. The great beauty of hypo—if it had any beauty—was that when once the salts of silver were in solution in it they never again, whatever degree of dilution were used, became insoluble.

After some further conversation on the subject the Chairman remarked that it was somewhat unfortunate that the specimens brought by Mr. Mainwaring were all more or less stained and discoloured.

Mr. MAINWARING said that he had done the whole thing in a hurry and not with the care necessary to secure perfect results, as he had not intended at first to mention the subject to the Society, his chief object being to satisfy himself.

The CHAIRMAN then asked if any member was disposed for a photographic trip to Stonehenge, and Wiltshire generally, as a gentleman who was going on a fishing excursion wished for a companion.

Mr. SHADBOLT then vacated the chair to read a paper on "Portraiture in the Open Air," chiefly devoted to a description of the mechanical contrivances for securing shade and shelter, consisting of light screens and canopy to be readily constructed and erected.

Mr. BOCKETT described a very cheap and efficient glass house he had constructed, which seemed to present many desirable points, and of which we hope shortly to give our readers a detailed description.

After some further conversation on the subject,

Mr. BARBER exhibited a sample of iodide of ammonium, produced by the double decomposition of sesqui-carbonate of ammonia and iodide of cadmium. He also mentioned that he had found that iodide of ammonium which had become slightly decomposed and brown from free iodine might have the free iodine removed and be made quite clean by washing with benzole.

Mr. MARTIN mentioned that ether answered the same purpose.

Mr. SIMPSON had used ether and found it left the salt very pure and white.

After some further conversation on this subject,

Mr. SEELEY showed a specimen of portraiture in an ordinary room.

After some further conversation the proceedings terminated.

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, May 27th, 1863.

THE programme of the conditions upon which the prize of 3000 francs, offered by the French Photographic Society for the best mode of producing enlarged positives, is now issued. It states that the object of the competition is to include both the optical and chemical means employed. The prize will be awarded to him who shall have resolved completely, either theoretically, capable of being practically worked, or practically only, the following questions relating to enlarging positives:—

- 1st. Shortness of exposure in the production of the *cliché*.
- 2nd. Freedom from distortion in the negative and in the enlarged positives.
- 3rd. Detail, equality, and sharpness in the image, as in the best proofs by the present direct method.
- 4th. Economical and practical production.

The prize will be divided among several competitors if they resolve any separate question, or in case he who solves the whole, shall have derived any portion of his operations from the ideas of processes of another. The prize will not be awarded if the solutions to the questions be not complete; in such case, the competition will be renewed.

If it be adjudged that none of the competitors have sufficiently satisfied the conditions of the programme to entitle them to the prize, it will be given, as an encouragement, one portion to the author or authors who have made the most important steps towards the solution of the problem, either by the discovery of new methods, or the improvement of those already known.

The competition is open to all the world, without distinction of country or nationality.

It will close on the 1st of October, 1865.

The members of the French Photographic Society will not be excluded from competing.

Communications must be addressed to the *Société Française de Photographie*, before the date above mentioned.

The processes described by the competitors in their communications will be kept secret only till the day of closing the competition but the Society do not intend to

deprive any inventor of the rights conferred upon him by any patent he may have taken out.

The communications, which will be addressed under seal, will remain unopened until the day of closing the competition, after which they will be opened.

At the meeting of the Society in July, 1865, a committee will be appointed to examine the various methods submitted to the Society, and award the prize.

The communications will not be returned, but deposited in the archives of the Society.

M. Kaiser, of Leyden, has made the following communication upon the iron developer combined with sugar of milk. He states that the unsatisfactory results given by sulphate of iron, dissolved in water acidulated by acetic acid, as a developer of photographic images formed in a layer of iodide of silver, have stimulated the production of several formulæ for the preparation of the iron bath. The reducing power of sulphate of iron alone upon the nitrate of silver is so energetic, that it must be diminished by some suitable substance. He is, however, convinced that acid is very injurious to the development of photographic images upon a layer of iodide of silver. If it be true that the iodide of silver, acted upon by light, is decomposed into iodine and silver or oxide of silver. The free acid in the reducing solution will remove a portion of the silver or its oxide, which composes the image formed, before the reducing agent has had time to develop the latent image. With a reducing solution which comprehends only substances which do not attack the silver or oxide of silver, the photographic image will develop itself after a shorter exposure, and even after a very short exposure, because, according to satisfactory experiments, the iodide of silver is instantaneously decomposed by light. The whole art of photography concentrates itself, therefore, in the art of *developing* the latent image produced by the shortest possible exposure to light.

I have found that sugar of milk does not act in any way upon silver or oxide of silver, and the preceding ideas have led me to replace the acids and other substances employed by sugar of milk. The results of my experiments have far exceeded my hopes, seeing that the image develops itself with admirable vigour and delicacy, after an instantaneous exposure. I have employed in these experiments a portrait objective, by Jamin, without diaphragm, for three-quarter plate, and the object photographed was a portion of the Botanic Garden at Leyden.

The employment of sugar of milk, as a substitute for acids, possesses the following advantages.

It is possible to develop a vigorous picture with a concentrated solution of sugar of milk, to which are added a few drops of a concentrated solution of sulphate of iron. The image will appear very slowly, and consequently be of extraordinary delicacy.

It is preferable to use a collodion not recently prepared,—that I made use of in the experiments referred to was nearly two years old.

A nitrate of silver bath of five or six per cent. will suffice, and it is no disadvantage if it contains a very large quantity of salts formed during constant use.

In a word, my iron bath possesses, as a developer, the advantages of the known pyrogallic acid and iron solutions, without their disadvantages. It will produce the latent image after an absolutely instantaneous exposure, without strengthening, and with a delicacy and clearness unattainable, by any other means.

M. Moisson presented to the Photographic Society several specimens of vitrified photography upon transparent glass. He states that he believes this kind of photography may be applied to the windows of apartments. The transparency, free from opacity, will be, he believes, an auxiliary which the glass-painter may advantageously employ. The method is as follows. After taking a transparent positive from a negative, either by contact or by the ordinary method, it is covered with yellow ochre, and when dry exposed to the

furnace in a muffle, until it becomes a cherry-red colour. When cold, the coating of yellow ochre is removed, and the picture is found vitrified.

IRON INTENSIFIERS.

DEAR SIR,—I feel confident that the method of intensifying with iron, recommended by Mr. Livesay in your last number, will be found to be a great improvement on the plan of using the acid exclusively in the iron solution. On reading your article on Mr. Blanchard's suggestion, I intended to have written to you, to recommend that part of the acid should be mixed with the iron, and part with the silver solution; if there is a sufficient proportion of acid in the latter, it may, if required, be added freely without making a coarse granulated deposit, such as is produced by the addition of plain nitrate in too large amount for the acid contained in the iron solution.—Yours truly,
C. RUSSELL.
May 25th, 1863.

THE DOUBLE SULPHITE DEVELOPER.

SIR,—I have read several times in the PHOTOGRAPHIC NEWS the method of developing negatives with the double sulphate of iron, so that they will not require any after-strengthening with pyrogallic and silver. I have tried several of the formulæ, and was at first inclined to think there was no advantage in it,—at the same time thought that it might be possible to do something with it, as I found the negatives developed very clean and bright, but came out very slowly. I therefore made several trials, varying the strength of the double sulphate. My last trial was as follows:—Double sulphite of iron 120 grains, acetic acid, glacial, 20 drops, distilled water 1 oz. I find that it is quite manageable at this strength, as it develops quickly and free from stains, and any amount of density can be obtained in a very short time by continuing the development, without the least fear of fogging the plate, and no pyrogallic is needed. The exposure is also shortened at least one half from the old method with sulphate of iron and acetic acid, and then strengthening up with pyrogallic and silver.

The enclosed print is from a negative taken with the above formula, and the time of exposure was for each picture two seconds with Dallmeyer's No. 2 B carte de visite lens, and No. 4 stop, which is about $\frac{2}{3}$ of an inch opening.

This picture was toned with—

Chloride of lime...	5 grains
Chloride of gold	2 "
Water	20 ounces.

This quantity will tone two sheets of albumenized paper.

I find this developer admirably adapted for instantaneous views. I will shortly send you a few prints from negatives I have taken with this process. If you think this of any interest to your readers, you are at liberty to use it.—We are, sir, yours respectfully,
BECKETT AND WILLIS.

32, St. Nicholas Cliffe, Scarborough, May 19, 1863.

[The prints received consist of eight card portraits of one person, each in a different position, on one large plate. Notwithstanding the large size of this plate, and the necessary lapse of time employed in posing the sitter eight different times, there is not the slightest stain, lack of brilliancy, or variation in quality, throughout the whole. Each one of the eight is a rich, brilliant, soft picture, well arranged and beautifully defined. The tone is a rich, warm black.—Ed.]

Photographic Notes and Queries.

TONING FORMULA.

SIR,—I shall be much obliged if you will give me your opinion, respecting the enclosed formula for toning bath, as I have never tried it. It runs thus:—

Solution No. 1.

Chloride of gold	15 grains
Filtered water	20 fluid ozs.

Solution No. 2.

Phosphate of soda	12 drachms
Distilled water	30 fluid ozs.
Refined borax	3 drachms

Warm the distilled water, and dissolve in it the phosphato of soda and the borax, then add by degrees the solution No. 1. The bath should be used slightly warm, and the prints must be watched, as they immediately take the desired tone; they must then be fixed in a twenty per cent. solution of hyposulphite of soda. The prints must be thoroughly printed till they have almost a steely tone; when removed from the frame they should be washed in a three per cent. solution of salt and water for ten minutes, then in ordinary water, and afterwards toned, and proceed as above.

I do not understand what is meant by steely tone.—I am, sir, yours respectfully,
G. COURT.

[We have no doubt that a solution prepared as above will tone well, but will probably not keep. The term "steely" means, doubtless, very dark and with a metallic lustre.—Ed.]

TONING FORMULA.

SIR,—I send you a new toning bath, which seems to answer admirably—chloride of gold, one grain, chloriato potass, thirty grains, water, six or eight ounces. Take the prints from the frame, and immerse them in water, and from the water to the toning, i.e., don't change the water. This bath works best when old.—Yours respectfully,
PUBLICOLO.

SENSITIVENESS OF SULPHO-CYANIDE OF SILVER TO LIGHT.

SIR,—In your paper read at the meeting of the North London Photographic Society, you stated you had found the sulphocyanide of silver was not affected by the action of light—that being contrary to my previous experience, I tried it this morning. I precipitated some sulpho-cyanide by adding sulpho-cyanide of potassium to solution of neutral nitrate of silver; dissolved the precipitate in ammonia, and crystallized it by evaporation, for the sake of getting it pure. To a solution of ten grains in liquor ammonie, I added one-half grain of nitrate of silver, and applied it by brushing to a piece of plain Saxe paper washed free from salt. The result was, it changed through various shades to a deep violet, in the course of about twenty minutes.

Probably yours did not blacken from the absence of organic matter, which we know is essential in many instances.

Yours, respectfully,

JOHN RUDDOCK.

[In the experiment detailed you did not expose simple sulphocyanide of silver to light, but that salt in combination with ammonia and nitrate of silver. The latter two agents applied to paper would have blacked without the presence of the sulphocyanide, so that the experiment proves nothing. If you refer again, however, to our paper, and to a note which accompanies it, you will find that we state that sulpho-cyanide did darken slightly in sunlight, and it is quite possible that it would do so more energetically if exposed in combination with organic matter.—Ed.]

Talk in the Studio.

LECTURES ON THE PISTOLGRAPH.—Mr. Skaife, who has opened a new studio in Sussex Place, Regent's Park, intends there to deliver a series of lectures on photography, especially in connection with its minute phases, to which he has given especial attention. The first lecture was delivered on Monday, the 18th instant, the chair being taken by Sir David Brewster, who, with several other savans interested in photography, amongst whom were the Bishop of Tasmania, the Rev. J. B. Read, Dr. Cronin, Dr. Purland, and others, was present. Mr. Skaife gave an interesting sketch of the origin of the pistolgraph and of his photographs of the firing of a mortar, its difficulties, dangers, and success. He also related an anecdote of his photographing, with his little instrument, Her Majesty as she was at full speed on her route to Wimbledon, and the risk incurred of being apprehended for an attempt to shoot the Queen. The lecture was illustrated by specimens and demonstrative experiments.

To Correspondents.

POSITIVE.—The formula to which you refer was, as we stated, given at a photographic meeting. We have not tried it ourselves. The strength of the developer, need not, however, in any degree affect the strength of the silver bath used. A bath for positives may contain from 35 grains to 40 grains of nitrate of silver, with from 1 to 2 drops of nitric acid to an ounce of water.

ALABAMA.—The recent decision of the judges regarding photographic piracies of engravings simply determines that when a copyright exists a photographic copy is an infringement of it. Where, from non-compliance with the provisions of the Copyright Act, or other causes, no copyright exists, photographic or other copies are not piracies.

P. T.—It is better to buy marine glue than to make it. It consists of 4 drachms of india-rubber cut into small pieces and dissolved in 4 ounces of benzole, to which 8 ounces of powdered shellac are added, the mixture being melted together by heat. It is then poured out into cakes to solidify. It may be bought at many tool-shops. 2. Glue would be dissolved by steam. 3. It is not injurious to prints to dry them upon blotting-paper. 4. They will not injure by being kept a few hours damp without spreading out to dry; but the sooner they are dried the better. 5. Solutions of carbonate or phosphate of soda do not injure by keeping. 6. The yellow brown precipitate in your developing solution is peroxide of iron. Filter it from the solution. That which forms a hard coating on the bottle may be easily removed by sulphuric acid. 7. The black powder thrown down by sulphate of iron from old toning solutions is metallic gold. The yellow or brown powder may be a little oxide of iron. 8. Your prints must be washed each time with fresh water. The silver in the washing water may be thrown down as a chloride. 9. Your last question, "May I register the colour of prints?" we do not quite understand.

GEO. ATKINS.—We do not quite understand what kind of stains you refer to as occurring always with a new bath. Stains should not so occur. They may sometimes occur from the bath not being saturated with iodide, or from the bath not being sufficiently acid; or possibly from using a developer with alcohol in it, which is unnecessary with a new bath. 2. Old silver baths should not be used for intensifying, but a fresh, pure solution. 3. The print enclosed is very good in some respects, but the lens is of too short a focus for a standing card figure. You may help it a little by using a camera with swing-back which will assist you in getting the feet in focus, as will also a small stop. The No. 1 B of the maker you name may, we believe, be used for card portraits with a distance of 12 feet between the camera and sitter; but the maker can doubtless tell you accurately. If you could in any way contrive to get a foot or two more it would enable you to work with more comfort.

No. 290.—It is evident that you do not tone to nearly a sufficient depth. Let the prints attain a black tone before leaving the toning bath. Read the chapter on toning in our ALMANAC. See also an article on toning which will appear in our next. Avoid the carbonate of soda as a rule.

B. W. S.—The negatives of your card portraits are pretty good, especially the two male figures. Your prints are, however, a little mealy. We shall have something more to say on the subject of toning and meanness in our next. Where you use a pictorial background, involving distinct perspective lines, such as an interior with receding wall, avoid using a carpet with a marked pattern, or anything else which will at once show that the point of sight in the actual photograph and that in the painted accessories are not the same.

H. CRESSON.—The chief cause of your printing difficulties is in your negatives: they are much too weak to yield brilliant prints. You must print very much deeper than you have done in the examples forwarded, and then tone to a deeper colour. It is generally desirable to have some brouzing in the deepest shadows in order to obtain vigorous and richly coloured prints. The behaviour of your hypo solution suggests the probability of some cracks in the glaze of the vessel in which it is kept. It will quickly attack and destroy the glaze of some inferior samples of earthenware. It should not have behaved as you describe otherwise. We do not think it will pay you to recrystallize your hypo simply for the purpose of fixing negatives.

EMILY.—We do not quite understand your difficulty in making chloride of gold. Is it that decomposition occurs whilst evaporating it, causing a precipitate? If that is the case you have probably used too much heat, or possibly added too much carbonate of soda in attempting to neutralize the acid. 2. Much depends upon the tone desired, as to which will be considered the best toning formula. Many persons prefer that with acetate of soda and gold, it generally gives various tints of purple. The solutions containing lime generally give black tones. You will find Ommegance's, Maxwell Lyte's, and many others in our ALMANAC for this year, where also you will find excellent collodion formulae. 3. The subscription to the Photographic Society is a guinea a year, and a guinea entrance. Dr. Diamond, the Secretary, will supply you with information as to the rules.

A. A.—In speaking of "a lens from a common stereoscope" you are much too indefinite, as many forms of lenses are used in that instrument. In some cases half a double-convex lens is used, in some simply a prism; in some a whole double-convex; in some a meniscus. In almost all cases the lens is non-achromatic, and the visual and actinic foci not coincident. It is most probable that to this cause your failure to use it satisfactorily as a landscape lens is due.

EPSTON.—We cannot give you the slightest idea as to the trustworthiness of the various descriptions of second-hand apparatus in advertisements. The best plan, for certainty, is to see the articles before you buy them. We cannot tell you the commercial value of the lens to which you refer. Your best plan, if you wish to make an exchange, will be to apply to some dealer of second-hand apparatus, such as Mr. Morley, who will, doubtless, deal fairly with you. A single lens is better for general landscape purposes than a portrait lens. The especial advantage of the triple over the single lens is that it includes a wider angle of subject, and is free from distortion, giving rigidly straight lines in architecture, &c., which no form of single lens ever does.

A. LUNATIC.—In what condition your negatives originally were, or what causes have been in operation to produce their present deplorable state, we cannot conceive. Moistening a film varnished with spirit varnish with spirit ought to have no more power upon it to produce cracks than the original varnishing had. Possibly your film, consisting of a piece in the

middle of the plate, allowed the spirit to get under by running all round the edges. Possibly it had not been varnished with a spirit varnish before. Apart, however, from the cracks, you have obtained very bad results. Either you must have continued the application of the iodine too long, or the plate had been treated with bichloride of mercury. Instead of obtaining a dense olive-coloured image, you have an image of pale yellow. Your original negative must have been sadly wanting in sharpness and vigour. We have had communications from several readers, amongst whom are very able professional photographers, who have succeeded in making worthless varnished negatives give very fine prints by applying the iodine solution as directed.

A. CONSTANT SUBSCRIBER.—Your only cause of failure is under-exposure, with, possibly, little under-development. So far as we can judge by the results, your bath is in right condition for positives. It is possible that your collodion may be old and insensitive, but as you do not state the length of exposure, we cannot form an opinion on that subject. In any case, with the same materials, a considerably increased exposure, and a little longer development, will give you good results.

JOHN CLESKY.—See answer to P. M., in our last. 2. We believe that the argentiometers are generally sufficiently accurate for testing the printing bath.

F. T.—The fee for registering a photograph is one shilling; the blank form costs a penny; and attendance in person or by an agent at the Register Office is necessary. If you fill up a form properly and send it with 15 penny stamps to our publisher he will register the picture for you. See form in our ALMANAC. The same fee is charged whether the picture be large or small.

P. G.—The reticulation of the collodion film on drying arises from the presence of too much water. The alcohol is not sufficiently highly rectified. When the tendency exists, you may, to some extent, ameliorate it by letting the film set well before immersion in the nitrate bath, and by giving plenty of exposure, so as not to need over-pushing in development.

J. R.—The question "whether photographic chemicals spoil by keeping" is rather a wide one. Some chemicals do spoil, and some do not. As a general principle, they do keep when unmixed. Some samples of collodion do not keep when iodized, or even when plain for very long. Ether is also apt to deteriorate by contact with light and air.

T. B.—The splitting and curling up of the collodion film on drying may generally be traced to one of two or three causes, or all combined. Imperfectly cleaned plates are the most common cause. Some samples of collodion have a predisposition to this defect. Pushing the development or intensifying will sometimes produce it. Besides avoiding these causes, you may prevent it, when the tendency exists, by pouring over the plate, whilst wet, a weak solution of gum arabic or albumen.

M. WYNTER.—On adding carbonate of soda to a silver bath containing acetic acid, acetate of silver is formed. A portion of this remains in solution, but if the acetic acid and soda are present in excess, a precipitate of acetate of silver is thrown down, which is the salt you enclose. It is a difficult thing to eliminate acetic acid from a bath. The only plan we can recommend is to add carbonate of soda until it is neutralized; then let the solution stand in a very cold place for a while, and filter out the precipitate. A portion of acetate of silver will still remain in solution. This may to some extent be got rid of by exposing the bath to sunlight for a few days, by which the acetate of silver will be blackened and thrown down. Again filter, acidify again, if necessary, with dilute nitric acid, and avoid the addition of acetic acid to the silver bath in future.

B. B.—We do not know the specific tone to which you refer, without seeing it. But it is most probably obtained by the acetate bath. Good negatives are essential to good tones, with these, good paper, strong silver solution, and deep printing, you may obtain almost any tone you desire. The tone of your print is not bad, but the negative is hard and not well defined.

H. HIGGINS.—We forwarded the stamps to Dr. Diamond.

PHOTO.—Pinholes arise from many causes, excess of acetate of silver, or of iodide of silver in the bath; dust, turbid collodion, bath, or developer.

T. LEDERSTERN (Cape Town).—Mr. Blanchard will shortly furnish us with a detailed description of his developing box.

T. A.—We will forward the last communication also to Mr. Glaisher. It is a subject we cannot enter into at length in this column.

C. F. LINCOLN.—The two samples of glass are much too light in tint, and would be worthless for the dark-room. A deep orange, approaching scarlet, is the right colour.

REVISED. and will be noticed in our next. "Adjutant or Photographic Art-Studies," Birmingh. "The Universal Text-Book of Photography," Harvey, Reynolds, and Fowler. "A Simple Practical Guide to Photography," by J. Fallowfield, and some other matters.

R. J. K.—To ascertain accurately the amount of angle included by any lens some elaborate mathematical calculations are required. If you have access to a table of sines it may be ascertained more simply. Ascertain the equivalent focus of the lens, and measure the base-line, the angle of subject included is twice the tangent of half the angle. If you are not a mathematician we may aid you in forming an approximation, thus: if the base-line of the picture is the same length as the equivalent focus of the lens, the amount of angle included is about 53°; if the base-line be half the length of the equivalent focus of the lens, the angle included is about 27°, and so in the intermediate proportion, not in definite ratio, but still near enough for a rough calculation. 2. Chloride of calcium and chloride of lime are not the same thing. The latter sold as bleaching powder, is used in toning baths. Its tendency is to give black tones. 3. We do not consider your collodion over-iodized, but in using the iodide of potassium and bromide of cadmium you will be apt to get a precipitate of bromide of potassium.

A. B.—Thirty-six letters for an advertiser with these initials, whose announcement appeared in a recent number of the PHOTOGRAPHIC NEWS, now lie at our office awaiting him.

Several Correspondents in our next.

TONING EXPERIMENTS.—BLACK TONES.

The theory of alkaline gold toning remains but very imperfectly understood. Whether it simply consists of a deposition of gold on the surface of the print, or is the result of a substitution process, an atom of gold taking the place of an atom of silver; whether the solution should be just rendered neutral, left faintly acid, or decidedly alkaline; what is the change which is produced by age on solution of gold and some neutral salts; what is the cause of the variety in tint produced by the different agents used in neutralizing or decomposing the chloride of gold—these and some other important questions, depending for their solution upon a satisfactory knowledge of the theory of the process, must remain undecided, until the subject is better understood. We shall probably have something to say on the theory shortly. In the meantime we have a few more words to say on the practice.

It seems to be pretty generally acknowledged that the base of the neutral or alkaline salt added to the chloride of gold does influence the colour of the resulting picture. Whether by regulating the degree of subdivision and size of the particles in which the gold is deposited, or by influencing its mode of combining with the particles of silver in the image; or in some other way, seems to be undecided. But the fact seems to be as generally acknowledged as that the acid in the developer affects the colour of the negative. The acetate of soda and citrate of soda tend to give purple tones; purple-brown if the print be lightly toned, purple-black if the print be deeply toned. The carbonate, phosphate, and biborate of soda have each slightly different effects, more running on the sepia tints. The presence of salts of lime seems to aid in producing pure neutral blacks, such as are familiarly known amongst English portraitists as the French tones. Which class of tones is considered best must depend largely on taste, but as a rule the public demand the black tones, and professional portraitists are therefore fain to produce them, and it is on the production of these tones we now offer a few hints.

We have recently been much interested, during a visit to the Isle of Wight, by examining the results of a very extensive and systematically conducted series of experiments in toning, chiefly conducted with a view to the production of pure black tones, without any red or brown tint on the one hand, or any blue, grey, or slaty tint on the other. These experiments had been conducted in the printing establishment of Mr. Jabez Hughes,* and under his direction, by his son, Mr. Alfred Hughes, and an assistant, Mr. Winterbourne. A general course of operations having been prescribed, each assistant carried out his own experiments independently and without any consultation as to details, or comparison of results until each series was completed. As every photographer knows, a certain formula may work well with a certain sample of paper, but gives

worthless results with another. In these experiments, therefore, a great variety of papers of different qualities, and prepared by different houses, were used, in order that a formula of most universal application, and one which seemed least deranged in its operations by accidental varieties in the paper, might be obtained. The results aimed at were a pure black tone, freedom from mealiness, very little bleaching or reduction in the depth of the print, uniform results on different papers, and a solution which, whilst it would tone soon after mixing, would also keep.

In one series of experiments seventeen different solutions were tried, and ten different samples of paper. In the other series thirteen solutions, and ten samples of paper. Without entering into a precise detail of some hundreds of experiments, we may state broadly their direction, and generalize the results.

Carbonate of soda added to a gold solution in sufficient quantity to neutralize any free acid, nor even in quantity equivalent to the amount of chlorine in the salt of gold, did not, according to expectation, produce a satisfactory toning solution, mealiness being a common result, until at least ten grains of bi-carbonate of soda were added to each grain of chloride of gold, even when the aid of heat was called in to facilitate the necessary reactions, prior to immersing prints. The tones given when carbonate of soda and gold only were present were invariably different tints of brown. The addition of chloride of lime, however, effected a great change and improvement in the character of the solution, black tones were obtained and more regular action. A solution made with from ten to fifteen grains of carbonate of soda, and three grains of chloride of lime to one grain of chloride of gold, in six or eight ounces of hot water, gave very good results. Its keeping qualities were uncertain, but a somewhat remarkable fact was observed, namely, gold solutions containing carbonate of soda, which generally decomposed, became stable when chloride of lime was added.

Chloride of lime alone with the chloride of gold, in any proportion, was found to be unsatisfactory, giving mealy prints when used at once, and not getting into working condition with any amount of keeping which had been tried.

Carbonate of lime and gold alone were not found satisfactory, even when hot water was used. But carbonate of lime, with chloride of lime and gold, gave the best results of all, the toning was moderately rapid, the colour a pure neutral black with warm fleshy half-tones. In this experiment pure carbonate of lime, as sold by the chemist, the same as prepared freshly in the laboratory, by treating common whiting with nitric acid and then precipitating it with carbonate of soda, and also common whiting as sold commercially, were all tried without any perceptible difference in the result. Various proportions were tried, with more or less of success, but the use of excess of the lime salt with hot or boiling water digesting it for about five minutes, and afterwards adding the chloride of lime, was found to be the most efficient method

* We may here remark that the experiments in question were undertaken with the express view of obtaining trustworthy formulæ for a new edition of Mr. Hughes' Manual, shortly to be published.

of getting a bath ready for immediate use. Perhaps the best formula, as deduced from the experiments and confirmed by our own practice, stands thus:—

Chloride of gold	1 grain.
Carbonate of lime from 3 to	6 grains.
Chloride of lime	3 "
Water	6 ounces.

This, if made with hot water, may be used soon after mixing, and will also keep.

Whenever a bath was required for immediate use, it was found that heat was a substitute for time, and a bath which, if made with cold water, might require some hours or even days to attain its proper condition, might, by the aid of boiling water, be made to work well, in a few minutes sometimes, and in an hour or two always. It may be fairly assumed that where heat is used the keeping powers of the bath will be impaired, but we cannot speak with certainty as to this being universally so. A singular point in regard to the keeping of gold solutions may be mentioned, namely, that in solutions which, if mixed and left without using would decompose and precipitate, the gold became stable if used for toning a few prints and then kept. The acetate bath, which is generally stable, was, with the especial sample of the chemicals in hand in Mr. Hughes's establishment, in the habit of decomposing soon after it was made, unless a few prints were toned at once. It then kept perfectly.

The general results we have described are deduced from the whole of each series of experiments, and it is interesting to state that without the slightest collusion or consultation between the experimentalists, the conclusions suggested by each were perfectly in harmony, the lime bath we have described giving the best results in each series, and we have since confirmed it by independent experiment. We may here mention one point in which our own experience is at variance with the results at Ryde, in reference to the proportion of carbonate of soda necessary to produce good results. We found, with the sample of chloride of gold we are using, that with two grains of bi-carbonate of soda and one grain of chloride of gold mixed in six ounces of hot water, and then two grains of chloride of lime added, a bath may be made which gives excellent results within an hour, and does not decompose in the course of a few days.

Our readers will distinctly understand that all remarks here have had reference to black tones. To those who prefer the warm and rosy purples we can recommend nothing which surpasses the bath of acetate of soda and chloride of gold.

One word of caution as to the use of chloride of lime. It must never be used in excess. For whilst the presence of free chlorine is necessary to toning, mealiness is the inevitable result of excess. Wherever silver in a state of fine subdivision is brought in contact with a bath containing either hydrochloric acid or free chlorine, the silver will be attacked, and mealiness will be the result. We feel satisfied that this is the chief cause if not the only cause of mealiness. To be perfectly satisfied, make a strong solution of chloride of lime, and in it immerse an unfixing and untoned print. The experiment is worth trying and will be suggestive and instructive.

Critical Notices.

ADJUTOR. A Monthly publication of Photographic Studies from Nature. Photographed by BRUNELLER and FISCHER. London; L. Birnstingl and Co.

WE welcome this publication with much pleasure as well-intended and giving promise of good execution. Its aim is to extend the usefulness of photography as an aid to art. It is to be a helper, and hence, we presume, its somewhat odd title. An extract from the preface—which is given in English, French, German, and Italian, indicating the universality of its aim—will perhaps best explain the intended scope and purpose.

We wish to furnish artists not with subjects for composition,

but merely with studies from Nature, comprising poses, animals, flowers, prints, landscapes and perspectives. We shall also delineate still life, antique and modern furniture, draperies in different materials, &c.; in short, we have resolved to publish all that photography can represent, which may be useful to the artist, and thus furnish him with a faithful copy of the original under the different aspects of light and shade. If we admit that photography is a faithful agent in the fullest acceptance of the term, it is easy to perceive how valuable our publication will become to the artist, as it will enable him to have at his command different objects, of which he can take advantage either to alter, modify, combine, or even copy, according to his pleasure; or by comparing one study with another, he will be able to introduce whatever may appear most suitable to his subject.

The first number before us contains five studies, the size being about 8 by 6, mounted on plate-paper about 16 by 12, with india-tinted margin. The subjects include two, or rather three, life studies, and two studies of still life. The life studies comprise a fine picture of a graceful girl well posed, and photographed with much delicacy. A male figure, nude from the waist upwards, with a fine head and chest, the arms illustrating great muscular action, the expression being in perfect keeping. This is a very fine photograph—the best of the series. A cow and landscape are a little wanting in vigour. The still-life studies consist of a portion of a drawing-room interior and a group of fish, &c. The photography is generally very good, and the subjects well chosen and arranged with great artistic feeling. In some cases, perhaps more might have been desired of the lenses. In the interior, for instance, we are struck with its fragmentary character compared with those which Mr. Hughes recently obtained of the bridal apartments at Osborne, in which, by the use of a lens embracing a wide angle, portions of three sides of a room are obtained and well defined, without distortion. Altogether, however, *Adjutor* promises well. There is ample room for such a publication, and we shall look for its further successful carrying out with interest.

THE UNIVERSAL TEXT BOOK OF PHOTOGRAPHY.

Instructions, Hints, Formule, and useful information on the various Photographic Processes, &c., with a chapter on the Aesthetics of Photography, from the French of M. DISDERI. Leeds: Harvey, Reynolds, and Fowler.

THIS is rather a text book than a manual for beginners, although it devotes a few pages to preliminary instructions. The aim of the compiler has manifestly been to secure comprehensiveness, almost every branch of photography receiving more or less attention. For the young student we should almost fear an *embarras de richesses* which might bewilder him; the more so that in the aim to include everything, scarcely sufficient care has been given to the construction and arrangement of the book. It is somewhat like a well-filled carpet bag, full of valuable matter, but in a somewhat crushed and mixed condition. Photographers of an experimental turn of mind will revel in such a book, as it is full of varied receipts, many of which are very good. In addition to an immense mass of matter on processes, there is a very interesting chapter on the aesthetics of photography, from the French of M. Disderi, some portion of which we shall, when we have space for the purpose, transfer to our pages. We can recommend the "Universal Text Book of Photography" as an exceedingly cheap shilling's-worth of matter.

A SIMPLE AND PRACTICAL GUIDE TO PHOTOGRAPHY. By JONATHAN FALLOWFIELD; edited by W. HUNT LEE: South London Photographic Depot, Lambeth.

THIS little work appears to be really an introduction to a catalogue of photographic chemicals and apparatus, and consists of less than a score of widely printed pages. The system of adding a few instructive pages to the trade catalogue is

becoming common, and is by no means a bad one, provided it be well done. We regret that we cannot say this much for the little work before us; for, although the matter is pretty well selected, and the plan of the work good, it is not unfrequently disfigured by obscurity, bad grammar, and plagiarism.* Such a passage as the following is downright nonsense:—

It may not here be deemed quite out of place to caution amateurs and others, desirous of obtaining satisfactory results, against the purchase of their materials, &c., at establishments where the exorbitant prices charged, or the numerous adulterations practised, render the efforts of the most careful manipulator worse than useless, and in many cases even the obtaining of a picture a matter of chance, which must always end in failure and disappointment.

In what possible manner can high prices, however undesirable in an economic sense, render the efforts of the manipulator worse than useless?

THE ROYAL YACHT AT THE NORE. Photographed by F. HAES. London: McLean and Haes.

Mr. HAES has sent us a very pretty vignette photograph of the Royal yacht, as she lay at the Nore, all her colours flying, with the Princess Alexandra on board. It is one of the best pictures taken on the occasion, which we have seen, although it lacks the action which gives interest to some of Mr. Blanchard's pictures of the same occasion.

PHOTOGRAPHIC CHEMICALS:

THEIR MANUFACTURE, ADULTERATION, AND ANALYSIS.

Sesquioxide of chromium is not only interesting on account of its being the tinctorial result of a very ingenious photographic process, in which bichromate of potash is reduced by the agency of light, but it is of value to photographers on account of its beautiful colour, which has caused it to be employed as a pigment. There are many ways of preparing this oxide, and as each process gives it in a slightly different physical condition, and therefore of a somewhat different tint, we will briefly describe some of the most approved methods.

Chromate of potash is dissolved in water to form a saturated solution; to this nitrate of suboxide of mercury is added until the precipitate ceases to fall. The liquid is then gently warmed and filtered.

The chromate of mercury is to be well washed and allowed to dry. It is then introduced into a glass retort and gentle heat applied. The hydroscopic water goes off at first and afterwards the salt begins to decompose. Mercury and oxygen gas are given off; the mercury condenses in the receiver, and sesquioxide of chromium is left behind, of a fine green colour. Another way to prepare this oxide is, to prepare a saturated solution of chromate or bichromate of potash and then to add a boiling solution of pentasulphide of potassium, to the boiling liquid, until no more oxide of chromium is precipitated. The reaction in this case is somewhat complicated: the sulphur is oxidized by half the oxygen contained in the chromic acid and is converted into sulphuric acid, which unites with the potash forming sulphate of potash, whilst the sesquioxide of chromium is precipitated. Some persons use pentasulphide of calcium for this process instead of pentasulphide of potassium, and maintain that it gives a brighter coloured oxide of chromium; in the latter case, however, it is liable to be contaminated with sulphate of lime. A third process, which is said to give a green of a peculiarly splendid colour, is the following:—Boil a solution of chromate of potash with sulphur until green oxide of chromium ceases to be precipitated; then filter and wash the chromic oxide till all soluble matter is removed; transfer to a dish or flask and boil in hydrochloric acid until

it has dissolved with formation of a brilliant emerald green solution of sesqui-chloride of chromium. Evaporate this solution to dryness, and ignite in a shallow dish freely exposed to the air. Hydrochloric acid will be driven off, and a beautifully coloured sesquioxide will be left behind.

Lastly, we will give a method proposed by Guignet for preparing a chrome green of a very rich and pure colour. A mixture of three parts of boracic acid and one part of bichromate of potash is calcined at a temperature of about 300° C. An evolution of water and oxygen gas is observed, and there is formed a double borate of sesquioxide of chromium and potash. This salt, which is stable at the ordinary temperature, is decomposed by water giving bichromate of potash and sesquioxide of chromium. The latter body in the nascent state combines with water and forms a hydrated sesquioxide of a remarkably fine colour. This is separated from the bichromate of potash by decantation and washing, and the remaining chrome green is allowed to dry at the ordinary temperature. This pigment is being largely used amongst artists on account of its beauty and brilliancy. The colour is very solid, and it has the valuable property of looking equally beautiful by gas or candle light as it does by daylight—the green colour not changing to blue as is the case with many pigments. Sesquioxide of chromium may also be obtained in a very curious form by the decomposition of bichromate of ammonia. A quantity of crystallized chromic acid is dissolved in water and divided into two equal parts, one portion is then neutralised with ammonia, the other portion added, and the whole evaporated over oil of vitriol. When the solution becomes sufficiently strong, the bichromate of ammonia separates in the form of large cherry-red crystals, which are collected by decantation, drained on bibulous paper, and dried at a gentle heat. On exposing a small portion of this salt to the heat of a spirit lamp in a platinum dish, a very energetic action takes place, accompanied by strong incandescence, and green bulky masses of chromic oxide shoot out in every direction, exactly resembling ordinary dried green tea leaves.

Sesquioxide of chromium possesses another property which renders it of interest to photographers. After it has been ignited it may be considered as being practically unaffected by any chemical reagent. It is, on this account, of the greatest value for colouring paper pulp, from which bank-notes, or important legal documents, are to be made. The green tint of the paper renders them incapable of being copied photographically, whilst the unalterability of the sesquioxide of chromium prevents the paper from being bleached by chemical means before taking the photograph. There is only one objection to paper tinted in this manner. The oxide of chromium is so intensely hard that it rapidly wears away the pens employed for writing on paper tinted with it. We are informed that the best osm-iridium-pointed gold pens become spoilt after being used for a few days in writing signatures on notes made of this paper.

The next metal which demands our notice, by reason of its photographic capabilities, is uranium. This formerly was looked upon as extremely rare, but of late years it has been procured in more abundance, and its salts are now to be met with, at a moderate price, at most operative chemists. The common ore of uranium is the mineral pitchblende. The composition of this is most complicated, for besides the uranium it may contain no less than twenty other elementary bodies, all of which have to be separated by complicated chemical processes. It would be quite out of the question for our readers, unless they possess more extensive chemical knowledge and more complete laboratory arrangements than fall to the lot of photographers generally, to attempt to prepare uranium compounds from the ore direct. The salt usually met with in the shops is the nitrate of uranium, a compound of nitric acid with sesquioxide of uranium crystallized with six atoms of water, the formula being:—

It is prepared by dissolving any oxide of uranium in diluted nitric acid, and evaporating the solution to the crystallizing

* In both the works on photography, we notice in this number, our YEAR BOOK is laid under contribution, in some cases freely, without any acknowledgment.

point. The salt separates in lemon yellow prisms with a tinge of green. It is probable that the proper colour of the crystals is pure yellow, but as this salt, in common with most uranium compounds, is very fluorescent when exposed to light containing much of the chemical rays, it is likely that the blue fluorescent colour, communicated to it in this manner, is the cause of its green tint, by conjunction with its original yellow. The crystals are acid to test paper. They deliquesce in a moist atmosphere, and dissolve in half their weight of cold water, forming a greenish yellow solution. The nitrate also dissolves with great facility in absolute alcohol and in ether. The alcoholic solution, heated to a temperature of 38° C evolves heat spontaneously, boils with the greatest violence, gives off nitrous ether, and deposits a very large quantity of a lemon-yellow powder, which is nearly pure sesquioxide of uranium. When the ethereal solution of nitrate of uranium is exposed to sunlight, nitrous ether is produced, a large quantity of the same yellow powder is produced, and there remains an aqueous solution coloured green by the presence of a lower oxide of uranium. When nitrate of uranium is heated, it melts in its own water of crystallization, gives off water and acid, and acquires a reddish yellow colour. When it is fused at a gentle heat, till the greater portion of the water is driven off a yellow liquid remains, which, on cooling, solidifies to transparent prisms. Upon exposure to the air, these rapidly absorb water, and lose their transparency.

REPLY TO MR. W. D. CLARK.

BY R. A. S.

MR. CLARK commences his paper with a complaint. "The discussion 'On Photography as a Fine Art,' has been conducted with too great a display of temper." I rather think Mr. Clark has mistaken for temper what impartial observers would characterize as simple earnestness and enthusiasm. I am not aware of any ease in which the advocates of photography, either as a fine, or, as a mechanical art, have overstepped the bounds of legitimate and logical discussion, unless indeed, Mr. Clark's own paper may be considered an exception, or Mr. Sutton's recent attack upon Mr. Rejlander can be so regarded; on which points however, lest I should offend, I will not venture to give an opinion.

Photography "looked upon as an intellectual pursuit is far inferior to that noble art," painting, because it is "entirely devoid of the beauty and expression to be got from the use of colour." Thus runs Mr. Clark's argument, No. 1. But what has this to do with photography as a fine art? Are Turner's monochrome sketches, Hogarth's engravings, Raphael's ink studies, and all those numerous works without colour, which are the pride of our museums and fine art collections, to be swept down from the lofty position awarded them by generations of artists and critics, because they "are entirely devoid of the beauty and expression to be got from the use of colour?" Argument No. 1 will not hold water, Mr. Clark.

"But this is not the chief disadvantage under which photography labours," says Mr. Clark, for the photographer cannot give expression to his subject, be it model or landscape, or, in other words, cannot convey "his own feelings and emotions" through the agency of his productions. Now, what can a lover of art-photography, who is familiar with the productions of Wilson, Bedford, Lake Price, Rejlander, &c., say to such an argument as this? He may point out the poetic grandeur and the romantic sentiments with which this, or that glorious photograph is overflowing, and he may turn over a folio of Rejlander's exquisite productions, in which the very expression, pose, chiaroscuro and sentiments of figures in the works of the best masters are faithfully reproduced from living models. He may bring forward these as unanswerable arguments, but what avails it if his prejudiced opponent only elenches his eyelids tightly over his spectacled optics, and says emphatically, "I can't see it, my dear sir, it's nothing but your imagination, I assure you." Has Mr. Clark seen these

productions? if not, before he writes another line against art-photography, let him do so. What better argument is there against the alleged impossibility of doing this or that, than the demonstrated fact of its having been already done. As to Rejlander's "Two Ways of Life," in which Mr. Clark could see nothing but mechanical "ingenuity," and before which he could do nothing but "wonder what it all meant," let him turn to the last number but one of the *British Journal*, and see what Mr. George Harvey, an artist of the highest repute, thought of this identical work.

Photography is not a fine art because it is not difficult of attainment. This is the novel test by which Mr. Clark discovers, in some mysterious way, whether an art may be called fine or not, and which test seems to have been originated by the writer having become mentally confused, and so thinking that arts which are attained with difficulty are more intellectual than arts which are attained more easily. The earliest sketch of a great master may have possessed more intellectual power and loftier art than the latest and most elaborately finished production of an inferior artist, whose long life had been one of ever-patient and earnest toil and drudgery. Shall we then say because the great master attained his art easily, and the inferior artist attained it with difficulty, that therefore the last was the greater? It is of no use for Mr. Clark to urge that photography is as easily acquired by great as by little masters, and that therefore, &c., &c. The test, the test's the thing, and that is clearly a failure.

The small angle of view and the other imperfections of lenses are next advanced as arguments against the claims of photography as a fine art. In reply to the angle of view argument, there is Sutton's panoramic lens, and Harrison's new globe lens; with regard to other imperfections Mr. Clark shall himself reply. In the exhibition of the Scottish Academy there are certain paintings held up by Mr. Clark as specimens of real fine art, one of which this gentleman describes as being "as true to the locality as any photograph." Well and good—if the painting be as true as the photograph, it follows that the photograph is as true as the painting, and if the photograph is not true enough to justify its claims as the production of a fine art, what is the painting, Mr. Clark?

"The irritability exhibited by photographers whilst urging the claims of their art to be included amongst the fine arts," is Mr. Clark's next argument as evidence of "a lingering suspicion that their cause is not a very strong one." Alas! for all sufferers from injustice, if the expression of natural indignation in the natural way is to be twisted and construed into a proof of having deserved ill treatment. When I am insulted I obey an impulse of my nature in warmly resenting it; am I to suppose that Mr. Clark would quietly pocket the same by way of proving his cause against the insulter "a very strong one." It is with me a subject of hopeful congratulation to know that photographers have sufficient respect for their infant art to resent an insult from those who would degrade and injure it in public esteem, warmly and enthusiastically.

At this stage of his progress Mr. Clark breaks off to diverge into a perfectly uncalled for and out of place attack upon the periodical literature devoted to photography in general, and the *British Journal* in particular, by which it appears that Mr. Clark may belong to a class by which joking is considered as sheer vulgarity, and cheerful laughter as a proof of downright ill-breeding. The mouths of our literary organs ought, perhaps, to be continually twisted into the "prunes and prisms" propriety of which Dickens has given us so vivid a picture in "Little Dorrit."

Returning to his subject, Mr. Clark thinks, after all, that although photography cannot rival, it may serve art, and also admits that no sketch can be so true to nature as certain photographs (taken by the aforesaid imperfect lenses) are. It is also admitted that "the exquisite detail that a photographer can obtain," in vegetation, &c., "no amount of care or finish will enable the artist to get."

Again, it is admitted that "photography is obviously doing good service to painting by educating the public eye to the beauty of simply an accurate copy of nature." But truthfulness, and beauty, and perfection of detail, are all as nothing in the eyes of Mr. Clark when considered as part and parcel of photography's claim to be considered a fine art. Photography is more truthful than Turner, says Mr. Clark, and the works of a fine art becoming through its influence more truthful, are thereby improved. Painting is to be tested by the standard of photography, says Mr. Clark, but the standard is decidedly inferior, and a long way below the thing tested thereby. Is all this quite logical, and does Mr. Clark really believe in the justice of his own cause?

AERIAL PHOTOGRAPHY.

For strategical purposes in time of war, and for the advancement of science in the nobler interests of peace, the balloon has proved serviceable; and the value of photography has now been tested conjointly with that of aerostation. Mr. H. Negretti, a partner in the well-known firm of Negretti and Zambra, the scientific instrument makers to the Admiralty, has performed some interesting experiments with the photographic camera in the car of a balloon. The pictures which he has succeeded in taking, at elevations ranging between 3,000 and 6,000 feet from the earth, are not, as may be imagined, perfect specimens of the art which he has helped in bringing to so fine a state of development on solid ground; but, considering the tentative character of his efforts, enough has certainly been accomplished to demonstrate the practicability of obtaining very good photographs of terrestrial objects at a height even greater than that which we have named as the maximum of his recent trials. Mr. Negretti, piloted by the experienced Mr. Coxwell, and attended by an assistant on whose ability he could rely, made his ascent from the Bell Green Gas Works, near Sydenham. The car of the mammoth balloon was fitted up as a dark room, and preparations for operating by the wet collodion process was made. It was not till an elevation of 4,000 feet had been attained that the rotary motion of the car ceased, or abated sufficiently to enable Mr. Negretti to expose the prepared glass plate. This was an anxious moment, for on the result of the first application of the developing fluid would depend the knowledge whether or not the actinism of the higher atmosphere was favourable to the operations of the photographer. The assistant soon dispelled this unpleasant doubt by announcing that the picture had "moved," or, in less technical phrase, that the image on the plate was ill-defined by reason of the unsteadiness of the lens. That there was an image, however, quite satisfied Mr. Negretti, who gave quick directions for the preparation of another plate. The second showed little or no improvement on the first; nor did a third or fourth bring any change in the assistant's gloomy iteration, "Moved." As the views were all taken instantaneously, it seemed difficult to account for the want of precision; and, on entering a stratum of cloud, the enterprising experimentalist was left to ponder the causes of the interruption to his complete success. On descending into clear atmosphere again—much clearer, indeed, than had been previously found—the attempts were renewed with better effect, and at last some tolerable pictures appeared on the filmy surface of the plate. The net result of Mr. Negretti's aerial essay is, as we have said, an establishment of the fact that photography is just as feasible an idea 5,000 feet above the level of the sea as in a commodious glass house in Regent Street or the Champs Elysées. The beautiful valley of the Medway has not been flattered by its *cartes de visite*, taken in the car of the mammoth balloon; but, on another sitting, its fair face may possibly "come out" more truthfully charming in the novel exposition of its loveliness.—*Télégraph*.

INCREASING THE SENSITIVENESS OF WET COLLODION PLATES.

BY THOMAS SUTTON, B.A.

[We extract from the last number of the *Photographic Notes* the following interesting paper. We have not had time to repeat the experiments, but as the subject is important, we place the matter at once before our readers for trial, and shall be glad to learn the results.—Ed.]

One of the directions in which photographers most anxiously look for advance in their art, is that of obtaining increased sensitiveness of negative plates and positive papers; our readers will therefore hail with pleasure the announcement that we have discovered a very simple means of exalting the sensitiveness of wet collodion plates, and at the same time introducing some other advantages. The method can be very simply stated, and very easily tried. It consists in first washing the excited plate thoroughly in distilled water,—or, which is the same thing, immersing it in a bath of distilled water,—and then re-dipping it in the nitrate bath; after which you proceed as usual. By adopting this modification of the common practice you increase the sensitiveness of the plate from fifty to a hundred per cent., and obtain a softer and more harmonious negative, with fewer pinholes and other common defects.

It will be interesting to discuss the *rationale* of this washing and re-dipping operation, as well as some other experiments which bear upon it.

If you take a collodion plate from the nitrate bath, wash it with water, expose it in the camera, and then attempt to develop the image in the usual way, you first find that it is absolutely necessary to add silver to the developer, in order to obtain a dense negative; and, secondly, that the sensitiveness of the plate is reduced, according to the amount of washing which it has received. This is the general statement of what happens to a washed plate exposed wet. You cannot *entirely* destroy its sensitiveness by *any* amount of washing, because you cannot entirely wash out all the free nitrate of silver; but by excessive washing, and exposing it wet, you can greatly reduce its sensitiveness, and render it almost impossible afterwards to get a good dense negative by any method of development. The presence of free nitrate of silver in certain quantity, in contact with the iodide or bromide of silver, is absolutely necessary, in order to get the most exalted sensitiveness of the plate. Again, if you take a thoroughly washed plate and endeavour to exalt its sensitiveness by applying to it any of the known preservatives, you fail in obtaining a satisfactory result if you expose the plate wet. The film must be allowed to become thoroughly dry before the plate is exposed, or it is next to impossible to get a good result. Of course, as the plate gets dry, the minute trace of nitrate of silver which it has obstinately retained, in spite of the washing, becomes concentrated, and in that state there may even remain enough in contact with the bromo-iodide of silver to render the dry washed plate as sensitive as the original unwashed wet plate. But this exalted sensitiveness which some dry plates possess depends upon their being quite dry, and is not observed in the same plates if exposed wet, or even damp. Everyone who has practised the dry process knows what a miserable result is obtained upon any part of a plate which has not become thoroughly dry, while the remaining part of the plate which is dry may yield a fine negative. The result is as true of bromo-iodized as of iodized collodion, and it proves that a certain quantity of nitrate of silver in contact with the iodide or bromo-iodide is necessary in order to obtain the highest degree of sensitiveness, and that the presence of bromide of silver alone does not *entirely* compensate for the removal of the free nitrate, as some people suppose.

Such are the observed facts as to the washing and drying of excited collodion plates, whether simply iodized or bromo-iodized. We now come to a new class of experiments, which consist in redipping in the nitrate bath a washed collodion plate before exposure; and this is found to render its

sensitiveness greater than it was at first, without introducing any practical objections. Moreover, the effect seems to be even greater and more decided with a bromo-iodized than with a simply iodized film. On considering this circumstance attentively we arrive at the following explanation of these facts:—

In the first place, there exists in the film, on its removal from the nitrate bath, a quantity of nitrate of potass, or cadmium, or ammonium, which no doubt, by its mere presence, acts mechanically in interrupting the chemical changes which occur during the exposure to light, even supposing that it does not act injuriously in any other way. This nitrate is removed by washing. Then again there may exist in the film some undecomposed iodide of potassium, or cadmium, which would be removed by washing, and the presence of which, in an unwashed plate, could hardly fail to affect the sensitiveness considerably. It is well known that a plate which has not been allowed to remain long enough in the bath is less sensitive than one which has remained the right time in it. And lastly, in the case of a bromo-iodized film, there is always a considerable quantity of undecomposed bromide of cadmium, or ammonium, in an unwashed plate, because, instead of minutes, it takes hours to convert the whole of this into bromide of silver.* We are the first to publish this strange fact, and although it was disputed at the time by some authorities, yet we observe that Major Russell, for one, has lately recognised it, for he directs his new bromized plates to be excited in a sixty-grain new nitrate bath, and left twenty minutes in it. Such treatment would be ruinous to an iodized film. Now all the undecomposed bromide of cadmium, in an unwashed bromo-iodized film, which has only been a few minutes in the bath, must surely interfere greatly with its sensitiveness, but it is removed by washing or soaking the plate in a bath of distilled water.†

Such are some of the reasons why washing and redipping the plate ought theoretically to render it more sensitive, and experiment proves that the treatment does so, and a very important result that is.

Another advantage of the treatment is, that it causes the developer to flow more freely upon the plate. The collodion film has naturally a repulsion for water, which is shown by the greasy streaks formed upon its surface when first dipped in the nitrate bath. This repulsion does not exist in consequence of the presence of ether in the film, because the same effect occurs when alcoholene is used instead of collodion, in which there is no ether present. Moreover, this repulsion is greater for water than it is for a strong saline solution like the nitrate bath. Thus it happens, that after all the greasy streaks have disappeared from the film on its removal from the nitrate bath, they reappear on immersing it in the bath of distilled water, and the plate has to remain some minutes in the water before they disappear again, when the water has permeated the film. Thus, after the plate has been redipped in the nitrate bath and exposed, the developer flows more easily upon it than if it had not been already permeated by water in the water bath.

It appears also that there are fewer pinholes and comets in a washed plate than in one which is exposed in the usual way without having been washed.

It only now remains to consider whether there are any practical inconveniences to put as a set off to the advantages gained by the additional operations of washing and redipping. But so far from there being any disadvantages, it appears to us that a great practical convenience may

* We must here interpose a comment. It is, of course, difficult to decide the exact point of time at which the whole of the bromide in a film is converted into bromide of silver; but all our experience goes to prove that although the decomposition takes place more slowly with a bromide than with an iodide, it is still a question of minutes not of hours. If it were otherwise the gradual increase of delicacy, softness, cleanliness, and, in some cases, rapidity, which is found with increased proportions of a bromide, would not, with an immersion of five minutes be perceptible as we have often found them.—ED. PHOTOGRAPHIC NEWS.

† We presume a fresh, unused bath is intended, otherwise the bath would contain portions of the nitrates here intended to be eliminated.—ED. PHOTOGRAPHIC NEWS.

arise from the plan recommended. Thus a photographer in large practice may clean and excite a number of plates in advance, ready for use as his sitters come in, and may keep them immersed in the water bath for hours until they are wanted; and when the time comes for using them, all he will have to do is to take them out of the water, drain them, dip them in a clean filtered nitrate bath, and put them into the dark slide. The time lost in coating and exciting plates whilst the sitter is waiting will thus be avoided, as well as the time lost in coating and exciting plates which are not exposed owing to defects in the film.

We sincerely hope that many of our readers will give this washing and redipping a fair trial. During the years which have elapsed since the original publication, by Mr. Archer, of the wet collodion process, no important modification of his original directions or proportions has been introduced. This is the first proposed change in the manipulation of that process which seems likely to be attended with solid advantage, in several ways, but more particularly in the increase of sensitiveness which it confers.*

The quality of negative is rather improved by the treatment, the contrasts being somewhat reduced, and more softness, harmony, and delicacy of detail obtained. With respect to the time which should be allowed for the plate to remain a second time in the nitrate bath, it should be remembered that the pores of the film are filled with water when it is first immersed, and time must be allowed for the nitrate solution to displace this water, or sensitiveness and density will not be obtained. On the other hand, if the film is left too long in the bath, the iodide of silver will be attacked. About half a minute will be found a good average time for the second immersion, or possibly less.

We shall be very glad to hear what success our readers have in trying the plan recommended in this article, and whether their experience confirms our own results. Should it do so our suggestions will have considerable practical importance. We would caution them, however, on this, and all occasions, to remember that in photography a single experiment proves very little, and that the results of such an experiment require to be confirmed again and again before they can be relied on. One of the evils attendant on photographic journalism has been, that persons are too ready to rush into print, and describe results which they have obtained, on the faith either of isolated or of too small a number of experiments. Many good processes have thus been condemned, and bad ones recommended, on the faith of a single trial.

HELIOCHROMY.

BY SAMUEL D. TILLMAN, M.A.†

TECHNOLOGY has its enthusiasts who are constantly claiming for it more than can ever be accomplished; they do not clearly perceive the line which limits the practicable. The actual success and great achievements of art afford them too much stimulus, and their imaginations seem to receive a momentum thereby which the judgment cannot check. The barriers disclosed on every side by test and practice present no impediment to their visionary advances. Having leaped over all obstacles to a satisfactory conclusion regarding some grand improvement, they receive with implicit faith every statement which tends to confirm it.

A few years ago the world was startled by a voice from the Highlands of the Hudson, announcing the discovery of a process by which light was made to give a permanent picture of any object in its true colours. Hardly had this voice been silenced when another was heard in a different direction; similar announcements have been made periodically up to the present time. The gentleman who has last

* Some years ago we made some experiments in a similar direction for the purpose of improving the character of collodion positives. Our plan was to use a very dilute second bath to lessen the amount of free nitrate left for surface reduction. We did not then notice any increase of sensitiveness; but we did not look for any.—ED. PHOTOGRAPHIC NEWS.

† Read before the American Photographical Society, April 13th, 1863.

agitated us on this subject is M. Niepce de St. Victor, whose reputation certainly entitles him to a hearing. He gravely states that he has succeeded in obtaining a pure and permanent black and white, with colours which were evanescent. Without questioning the correctness of this statement, or attempting here to account for the phenomena observed upon the principle of sympathetic molecular vibrations, it is safe to assert that the real problem is as far as ever from a satisfactory solution. It seems proper that practical photographers should have a clear comprehension of the proposed improvement and the difficulties attending all attempts to give it permanence. A few succinct statements may elucidate the subject.

1st. The action of light is through an undulating ethereal medium which produces three distinct kinds of effects, viz., colorific, calorific, and actinic.

2nd. The colorific effect resulting from the action of a single octave of waves, probably depends upon the harmonic relations arising from the ratio of the velocities of these waves. These waves produce the picture visible to the eye in the camera, but have little or no influence in producing the invisible effects made upon the prepared plate.

3rd. The waves of higher velocity possess actinic power, which is graduated by the sun of light sent from every point of the object to be copied.

4th. It is obvious that the actinic rays being the chief, if not the sole cause of chemical change, must impart their own characteristics to the chemical preparation to the exclusion of those belonging to colorific action.

5th. The ratios of velocities of waves exciting the impression of color are generally lost the instant these waves impinge upon the plate, as the ratio of falling drops of water disappear when the drops are commingled. Yet should the atoms of the sensitive film take up the vibratory motion of the impinging waves, the action could not be of long duration, because the same kind of matter cannot have various rates of vibration, each normal and lasting.

6th. Besides a change in molecular motion, we may imagine a change in the position and arrangement of molecules, so as to present a thin lamina, which may have the effect of decomposing light and sending out such delicate tints as come from the shell of the pearl oyster. It is possible that this mechanical change might be quite as permanent as the chemical change produced by the actinic rays; yet who has proved by experiment that æth-waves have the power of aggregating and dispersing molecules or atoms?

7th. The chemical changes produced by light can differ only in *degree*, owing to the homogeneity of the substance covering the prepared plate; and in this view of the case the scientist is safe in asserting that the colours of nature cannot be imitated, until we have more perfectly under our control the materials with which she works. Thus far, the few elements she uses in producing the gorgeous colours found in the vegetable kingdom have refused to acknowledge any other master. These colours are not superficial; they are the result of internal structure. The gradual and systematic arrangement of cells belongs alone to the power of growth. When man can weave atoms at his will, and combine elementary substances in ways which chemistry thus far has failed to do, he may construct the groundwork for a chromatic exhibition. But to prepare a surface with any of the compounds now known to the chemist, which will give back the whole gamut of permanent colours, is a proposition that should not be seriously entertained.

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, June 3rd, 1863.

DR. VAN MONCKHOVEN, experimenting upon formic acid in developers, both sulphate of iron and pyrogallic acid, states the result to be as follows:—Sulphate of iron develops the

negative more quickly than pyrogallic acid, whether the latter has acetic or formic acid added to it. It admits also of an exposure, one-third shorter, in the camera.

Pyrogallic acid, with formic acid added to it, makes the image appear quicker than with acetic acid; but formic acid, reducing the silver from its nitrate without, however, concurring in making the image appear, fogging often results. Although the addition of formic acid, in the place of acetic acid, develops the picture in less time, the exposure in the camera cannot be diminished. Thus, it appears that Mr. Claudet's formula does not possess the advantages he claims for it. On the other hand, Mr. Claudet assumes that the acid employed by Dr. Van Monckhoven was too concentrated. Possibly it was so. But as Mr. Claudet has not indicated the degree of concentration of the formic acid he employed, while Dr. Van Monckhoven, in the account of his experiments, took that precaution, the latter intends to repeat them, although he finds it difficult to admit that by diminishing the proportions of formic acid the exposure in the camera can be shortened.

With reference to the composition of the positive image on paper, Dr. Schnauss has stated that non-albumenized positive paper simply toned with chloride of gold, *either before or after fixing*, contains gold only, without appreciable traces of silver. But Dr. Van Monckhoven formally disputes this conclusion, at least, so far as relates to the words in italics. He maintains that only gold remains in the proof when it is toned *before* fixing, but silver remains *in the state of chloride*, if the picture is toned *after* fixing. This fact is explained in the following manner:—

The image, upon paper simply salted, is composed for the most part of metallic silver. Immersed in the chloride of gold, one portion of the gold is precipitated upon the silver, while the chlorine of the chloride of gold combines with the silver, and forms white chloride of silver and violet chloride of silver. If, however, the chloride of gold acts for a long time, this violet chloride itself takes more chlorine and passes to the state of white chloride. Then the hyposulphite, acting upon it, leaves only the gold.

But, on the other hand, the image first fixed, it is then wholly constituted by metallic silver, the chloride of gold acts in the same manner, and chlorides of silver and of gold are found in the proof. If, therefore, we do not have recourse to a second fixing, silver in the state of chloride remains in the proof. With albumenized paper, the reactions are more complex. It must not be forgotten that in this case we operate with chloride of gold only, and not with the alkaline gold baths usually employed.

Some of our photographers are busily occupied in producing the photographic postage stamp. Cameras and objects are specially constructed for this purpose, by which four-and-twenty pictures are taken at one operation.

Positives taken upon plain paper generally possess less brilliancy than those taken upon albumenized paper. It is not sufficient for the paper to contain chloride of silver with excess of nitrate; to obtain brilliant pictures, there must also be present an organic substance, capable of combining chemically with the nitrate of silver, just as the albumen does. The substances which accomplish this object, more or less, are gelatine, arrowroot, resin, gutta percha, caoutchouc, sugar of gelatine, decomposed nitro-glucose, &c. Very good results are obtained by immersing the positive papers for a few moments in a warm solution of gutta percha, or caoutchouc in chloroform and benzine, and when dried, salting them in a solution of an alkaline chloride. Sensitizing, and the other operations, are performed in the usual manner. The pictures thus obtained are, it is true, less brilliant than those with albumenized paper, but on the other hand, the paper is more reliable for use. In any case, the picture is infinitely more brilliant than with ordinary salted papers.

M. Testelin's article on developing and strengthening with sulphate of iron, inserted in No. 239 of the PHOTOGRAPHIC NEWS, is very complete and instructive; and in our present

state of knowledge respecting reduction, very little is required to render this kind of review of the processes employed perfect. The writer has noticed all the good methods of reduction, easy to follow, and giving remarkable results. Still, however, we find that he has not sufficiently recommended strengthening with sulphate of iron; therefore, we will describe yet another method preferable to the old one, which consists in continuing the reduction by means of pyrogallic acid.

The negative, as soon as possible after exposure, is developed by pouring on to it the sulphate as *slowly* as possible, without dividing or breaking up the stream. The surface must be covered with a light, but continuous layer, taking care to employ only a *small quantity of the liquid*, just sufficient to cover the plate with a slight excess. If the operator contracts the habit of pouring on the iron solution very slowly he may reckon upon a *diminution of the time of exposure equal to one-fifth of the whole*. The negative is slightly washed, then covered with a solution of nitrate of silver of the strength of 2 to 3 per cent: the operation is performed in the same way as collodionizing a plate. The excess is collected, then the iron solution is again poured on in the same way as described for the silver solution. If, after this second operation, the negative is not completed, we proceed to a third, and even to a fourth, until it attains the desired vigour.

It will be remarked that the negative being of a grey colour will not appear so opaque as those developed with pyrogallic acid. But this colour may be changed at the will of the operator by employing, in the last place, sulphate of iron with gallic acid, a bath which is rendered colourless by nitric acid. We may limit ourselves to passing the negative into a *very weak* solution of *bichloride* of mercury. It has become the fashion of late to deery the use of this latter substance on account of its causing opacity in the picture and liability to fade, but five years' experience have never shown us these objectionable results. Employed in a concentrated solution the bichloride acts in the same manner as a strong dose of pyrogallic acid in presence of nitrate of silver, by rendering the image opaque, but in a weak solution the bichloride blackens the image without being accompanied with this inconvenience.

In fine, strengthening with the sulphate of iron indicated above, is made with rapidity and certainty. It gives better results with portraits than pyrogallic acid yields, and its employment is free from the risk of failure.

The quantity of sulphate of iron composing the bath has little or no influence upon the final result when the quantity of acetic acid is in direct ratio with the sulphate. If it is from 5 to 10 per cent, there must be at least 2 to 4 per cent. of acetic acid. If the quantity of sulphate reaches 15 to 20 per cent, there must be 6 to 9 per cent, to produce the same effect.

When the bath is employed several days in succession, it is preferable to add from 1 to 2 per cent. of acetic acid, in order to re-establish it from day to day in its primitive condition.

In the proportions of 1 per cent of sulphate to 2 per cent. of acetic acid, we obtain an iron bath very nearly the same in its action as pyrogallic acid.

Some operators add a quantity of alcohol to the bath in order to equalize the difference of density between the liquids. Possibly, they may obtain a good result, but veins of a greasy aspect multiply upon the collodion film, the reduction becomes unequal, and failure is a very frequent consequence.

In practice, the following maxims are of very great importance:—

1st. That a negative developed an hour after exposure has lost much of its sensibility.

2nd. That in pouring the sulphate on slowly we obtain a negative with an amount of exposure which would only have yielded a positive, if the liquid were in large quantity and poured on rapidly.

3rd. That when we cover the film with the solution of nitrate, we strengthen the picture more quickly and with less silver than if, at several repetitions, it had been added to a portion of the iron bath.

4th. That a very weak solution of bichloride absolutely presents no inconvenience.

MR. CLARK AND PHOTOGRAPHY AS A FINE ART.

DEAR SIR,—In the NEWS of last week appears a paper read by Mr. W. D. Clark, before the Photographic Society of Scotland, entitled "Photography as a Fine Art." It seems to me that the effect of this paper, if uncontradicted in regard to many of its details, would be to convey very erroneous ideas of the present position, and probable future, of photography.

Not having the advantage of the personal acquaintance of the writer of this paper, and being quite unacquainted with his name, either as a photographer or a painter, I shall be excused from all animus in calling attention to some of his assertions.

Mr. Clark commences by drawing attention to the inferiority of photography to painting. Having yet to learn that the opposite has been asserted by any writer of authority, it may be assumed that it is a controversy of Mr. Clark's creation—a statement made in order to be denied. Photography and painting base their claims to support on entirely distinct grounds. They are the offspring of minds having totally different objects in view. I am inclined to think that, with Mr. Clark, familiarity has bred contempt; the fact of the enormous demand for photographs causing every shop to be filled with them. But let us for a moment suppose that one of these cartes de visite, of which Mr. Clark speaks so slightly, required months of labour to produce, and could then only exist as one single picture, without the power of reproduction, I feel certain that in such a case it would be pronounced the masterpiece of the most inventive age ever known.

Mr. Clark invites comparison between photographs and paintings; let us, therefore, examine a little into the question. The most immediately lucrative branch, both of painting and photography, is portraiture, and as there is just now a large demand, it is a matter worth consideration. Two exhibitions, one of photographs, and one of paintings, (the Royal Academy) have been opened this year within a few hundred yards of one another, and a very large number of persons must have visited both. I have most carefully analysed the manner of treatment employed by artists whose portrait paintings are now suspended in Trafalgar Square, and confess my strong belief that taking them, as a whole, neither the pose, accessories, nor yet the very point on which Mr. Clark relies most—the expression—are by any means equal to photographs of high class. Again, Mr. Clark exultingly declares that photographs have no power to "tell a story or appeal to the feelings." How then about Mr. Robinson's "Bringing Home the May?" I defy any unprejudiced person to assert that there is not in this picture the most exquisite "story" of rustic life, or to state it does not appeal to the feelings in the strongest and most forcible manner. Again, Lady Hawarden's studies are direct contradictions of Mr. Clark. In another branch, let us take the pictures of moving life by Mr. England and Mr. Breese. Surely that person must be wanting in every sentiment of beauty who can assert that these do not illustrate, in a manner never before dreamed of, the writings of poets in all ages. Few, very few, I am convinced, can look on these magical views of cloud, sea, and sunshine, without recalling our national "Rule Britannia," and an exclamation of delight at the exquisite beauty of the result. Painters may colour their brightest, and pre-Raphaelites may draw each blade of grass and every leaf with painful correctness, but I cannot allow that these photographs are produced by any other than a high feeling of reverence for the beauties of

nature. They most aptly illustrate many a line of poetry which is oftentimes offered at exhibitions.

One cannot be surprised that many painters should be found to deery the new art that has destroyed the practice of all second and third rate artists, whatever may be Mr. Clark's opinion. Mr. Clark says, "The world generally estimates the value of any pursuit in proportion to the intellectual effort employed in it." If this be the case, I am unable to see why photography should come off second best. I absolutely deny Mr. Clark's statements about the facility with which photographic excellence is acquired. On the contrary, it takes the experience of years to become anything like proficient. Let Mr. Clark take a few names of those who do the best pictures, and he will find that, without exception, they have been a considerable number of years. Of course, all know that certain results can be produced at first starting, but cannot the painter also do this? and shall we say that one and not the other can be learnt in a very short time? Mr. Clark is singularly unfortunate in his comparison of the pictures of the Holy Land and Egypt. The very same occurrence has happened in my presence that he describes, and where the result was totally different. Those who had travelled in the East immediately relinquishing Mr. Roberts's lovely pictures in favour of Mr. Frith's photographs. Mr. Clark says, "In figure subjects, photography can only copy, it cannot invent." This proposition appears like a formal denial that a photographer can be an artist in the true sense of the term. What is there to prevent a photographer arranging his models with as much skill as a painter? Of course the camera cannot invent, but, surely, he who uses it can.

Those painters and sculptors who are alive to their own best interests, use photography largely. A group now in the Royal Academy has absolutely the same positions, accessories, and expressions on the face as the photographer secured, although the painter was not even present. Mr. W. D. Clark's erratic and exceedingly crude remarks should be a caution to those who consider themselves qualified to act as a "guide, philosopher, or friend" to the artistic world in general, and photographers in particular.

SAMUEL FRY.

83, Gracechurch Street, E.C.

MR. BROOKES ON THE ACTION OF THE BLUE RAY.

DEAR SIR,—There were two points in the paper I read last Tuesday before the Photographic Society of London, upon which I seemed to be misunderstood. During the preparation of that paper, one of the knuckles of my right hand was so inflamed that I could not hold a pen, and had to obtain the assistance of a second person to copy from my rough jottings down. This copy I had not time to alter, and, whilst reading it before the meeting, discovered, besides numerous mistakes, whole pages left out.

The first mistake I wish to correct is in regard to that portion relating to "Ether." The impression I wished to convey was, that as phosphorus held in solution by ether decomposes the iodide film when only the *invisible fumes* reach its surface, so that element held *invisible* in the atmosphere likewise decomposes the iodide film when brought in contact with the rays of solar light.

Secondly, in respect to "*Phosphorus and Phosphorescence*:"—I am well aware that the latter term is applied to that light, which organic and inorganic bodies have the power of emitting after insulation to solar light. If I were understood to imply that this light is *phosphorus*, it was owing to my unfortunate lack of the ability of expressing my thoughts and ideas by speech. The following is what I meant:—That silver, whether in combination with iodine, chlorine, or bromine (and not simply these, but other bodies also), induce phosphorescence from light. (It matters not whether this is termed "*invisible phosphorescence*"); but, in this case, instead of giving back the light it has received from the sun, as in the *Bologna stone* and other phosphorescent bodies, enters into combination with the iodine or the silver. For the fumes or vapour of phosphorus being the slow combustion of that element in contact with the oxygen of the atmo-

sphere, and this vapour decomposing iodide of silver, which, according to Mr. Malone's statement, forms phosphate of silver; so the decomposition effected by phosphorescent rays of solar light upon iodide of silver, *may be*, identical to the similar displacement caused by the phosphorescent rays emitted by ordinary phosphorus.

It was this I wished to explain both by the paper and verbally; in endeavouring to do so by the latter means, I know "*I jumped from the frying-pan into the fire*;" and until I can read the paper in print, I cannot tell to what extent I was misunderstood, as I have no copy in my possession to refer to; but the above is what I still believe to be the cause of the decomposition of the iodide film, &c., and I hope, at some future period, to be able to prove such to be the fact by evident experiments.

Apologizing for occupying your valuable space with what ought to have been distinctly explained by me at the time, I am, dear sir, yours truly,

E. T. BROOKS.

Newbury, June 3rd, 1863.

Proceedings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

THE last meeting before the recess of the Society was held at King's College, on the evening of Tuesday, the 2nd inst., Mr. C. B. Vignoles, F.R.S., in the Chair.

The minutes of a previous meeting having been read and confirmed, Mr. Mason, of Blackheath, was elected a member of the Society.

The SECRETARY read a letter from Mr. Ross calling attention to a portfolio of photographs which accompanied it. They were taken with his triple lens; some with a lens of 8½ inches back focus intended to cover 8 by 4½, were taken on 12 by 10 plates: others on the same sized plates taken with the lens intended for 10 by 8 plates, the focus being 15 inches. He also sent a brilliant, well defined negative taken with a new portrait lens for medallion pictures, the focus being 1¼ inches and the diameter ⅝ths of an inch.

The SECRETARY also read a letter from Mr. Dallmeyer calling attention to a magnificent copying camera and equipment for plates 18 by 18, which he had just completed for the Italian Government. Also to some interiors of the bridal apartments at Osborne by Mr. Hughes, taken with his No. 1 triple, of 8 inches equivalent focus, on plates 10 inches square; and to some portraits of different members of the Royal Family, taken at Windsor with his No. 2 card lens, by Mr. Mayall.

The SECRETARY then explained that Mr. Smith, who it was hoped would have been present to exhibit and give the history of the photographs supposed to be taken by James Watt or Matthew Bolton in the latter half of the 18th century, was unable to enter into the subject at present, but would do so when he had further completed the history of the matter. He had, however, prevailed upon Mr. Smith to allow him to bring one of the paper pictures for the examination of the meeting.

After some conversation on the propriety of entering into any discussion of the subject in the absence of full details.

The CHAIRMAN expressed a conviction that it was quite competent for members to discuss the matter so far as it was before them, confining themselves chiefly to the question, was the picture before then a photograph or not; was it produced by the hand of man, or the pencil of nature.

Mr. SHADBOLT said that Mr. Smith having communicated to him various points of evidence in confidence, his mouth was sealed as to details, but he had no hesitation in expressing his conviction that the picture before them was a photograph and that James Watt was the inventor of photography in this country.

The SECRETARY asked Mr. Shadbolt if he did not mean Mr Bolton.

Mr. SHADBOLT was inclined to the opinion they were by James Watt.

The CHAIRMAN referred to the partnership of Bolton and Watt, saying that although the former was an excellent man he was more properly the man of capital and Watt the man of brains. As an engineer himself he should prefer to think it was he who invented this art 70 or 80 years ago.

After some further conversation on the subject,

Mr. G. WHARTON SIMPSON said he was afraid that the sub-

ject would be difficult to discuss satisfactorily in the absence of more evidence than was before the meeting. One or two others present and himself were in possession of many details they were not at liberty at present to make public; but he thought Mr. Shadbolt would agree with him that they might state thus much, that some of the pictures were labelled "Sun pictures by J. W." which seemed to settle that part of the question in favour of Watt.

Mr. SHADBOLT said there was even more evidence than that.

The SECRETARY referred to a process of copying mezzotint engravings by Mr. Bolton, which produced such accurate imitations they could scarcely be distinguished from the originals.

Mr. MALONE had examined the specimen before them, and could not help expressing great surprise that any one should take it for a photograph. It had more of the character of a drawing in liquorice, and had no resemblance whatever, that he could see, to a photograph.

After some further remarks,

Mr. SIMPSON said if the matter were discussed it should be distinctly borne in mind that it was not asserted that these were photographs by any process now known. It was simply stated that they were sun pictures, obtained in some way by the agency of light. Any deduction drawn from a comparison of these with ordinary photographs would be very likely to lead to error.

The CHAIRMAN said this was undoubtedly true, but still it might be possible to arrive at some conclusion from an examination of this picture as to whether it was produced by chemical action or hand labour.

Mr. MALONE said they could only examine it by the evidence before them, and on that evidence he affirmed that there was no reason to believe it to be a photograph.

The SECRETARY said perhaps he was to blame to bring this picture before them without being permitted to bring other evidence. There were, however, two Daguerreotypes, in all respects resembling the early pictures of Daguerre, but these were taken as early as 1791, one being a picture of Mr. Bolton's house before the alteration in 1791, and the other, which at first appeared to have nothing on it, was found, on careful examination, to be a picture of the house after the alteration. It was not until, in company with Mr. Thurston Thompson, he examined this in a strong light that he discovered anything on the plate at all.

Dr. WRIGHT called attention to the paper being common writing paper with a water mark, such as no one would have used for producing a finished drawing upon; if the picture before them were not a photograph it was an exquisitely finished drawing.

Mr. DEBENHAM said there were some minor stains and imperfections in the print before them which looked marvelously like those which would arise in photographic manipulation.

After some further conversation, Mr. ALLEN said that the print showed decided signs of being produced by the hand of man, all the touches of the brush were quite apparent.

Mr. SIMPSON said he was afraid that some members were looking at the picture as a photograph from nature, whereas it was a reproduction, a copy of a picture, and as such should of course accurately reproduce the touches of the brush.

Mr. HENRY WHITE expressed a decided conviction that it was a photograph. On examining it carefully it would be seen that the original from which this had been copied had a rough surface, and the small protuberances or excreescences each cast a shadow which was here accurately reproduced, showing that it had been taken by light. It would have been scarcely possible to produce such an effect by hand if it had been tried.

Mr. BROOKES had noticed the same fact and drawn the same conclusions.

Mr. SHADBOLT said that although they could not discuss the matter in its entirety, it might be interesting to restate the particulars which had already been published. (He here detailed the particulars which appeared on p. 193 of the PHOTOGRAPHIC NEWS, vol. 7, April 24th.) The evidence so far as it had gone was quite sufficient, he thought, to prove in a court of law that these were photographs taken by James Watt; but Mr. Smith thought he could make it better, or even indisputable. He (Mr. S.), as a photographer ever since the introduction of the collodion process, felt convinced that these were photographs in the most complete sense of the term, produced by the action of light.

Mr. MALONE reiterated his conviction that there was nothing to prove that these were photographs at all. The prominences referred to might be roughnesses in the paper where the colour had not taken well.

The CHAIRMAN referred to the fact that the pictures were not upon the paper itself, but upon some varnish or medium. Possibly some artist could help them by saying if any method of working on such a surface so perfectly were known.

Mr. DEBENHAM said if the prominences were, as Mr. Malone said, roughness in the paper, that might be ascertained by looking through. (This being done it was found that the prominences were not in the paper.)

Mr. BROOKES suggested that they might have been drawn by the aid of the camera lucida, and then both the correctness of the drawing and its reversed character would be accounted for.

After some further desultory conversation on the subject, it dropped.

The SECRETARY showed some instantaneous stereographs, by Mr. Davenport, of London Bridge, on the entrance of the Princess Alexandra.

Mr. BROOKES then read a paper on the action of the blue ray on the iodide, bromide, and chloride of silver, in producing the photographic image. The argument advanced was an ingenious one, but appeared to us to be based on a misconception of the exact meaning of some terms in chemical nomenclature.* He argued that as phosphorescence was the result of the blue ray it contained phosphorus, and that photogenic action was the result of minute particles of phosphorus in the blue ray diffused through the universal ether. To illustrate this he dissolved phosphorus in ether, and exposed an excited collodion plate to the vapour, he then developed it, and obtained a reduction similar to that produced by light.

Mr. DEBENHAM asked Mr. Brookes if he imagined the ether of the chemist was the same substance as that diffused through space.

Mr. BROOKES said "No," he had used the phrase rather as an illustration than as a statement of a fact.

Mr. DEBENHAM thought that all which had been proved by the experiments detailed was that phosphorus would fog an excited plate.

Mr. BROOKES said that he was merely quoting Dr. Phipson in ascribing phosphorescence to the action of the blue ray. If paper were treated with tartaric acid and then submitted to the rays of the sun, it would absorb light, which would afterwards have chemical action.

Mr. DEBENHAM said that M. Niepce de St. Victor's idea of bottled light was exploded.

The CHAIRMAN moved a vote of thanks to Mr. Brookes for his paper, and invited further comment.

Mr. MALONE remarked that Mr. Brookes laboured under a fundamental error of judgment in supposing that phosphorus existed in light, and in imagining that his experiment proved such a thing. Because he had produced a body resembling the photographic image by the use of phosphorus, he argued that light contained phosphorus. However plausible such an argument might appear at first glance, it was altogether fallacious. The salts of silver could be reduced by many agencies. The oxide could be reduced by heat; the chloride by heat and hydrogen, and also by light. But because phosphorus and other agents would reduce silver, was it to be argued that these agents were all present in light? He had used phosphorus for reducing silver, at a former meeting, but for illustrating a very different point. Mr. Malone then referred to Mr. Glaisher's experiment, and remarked that the result was most probably due to the dryness, as chemists had an axiom that without solution there is no chemical action. He then proceeded to describe some further experiments he had made, in verification of the theory he held that the photographic image was simply metallic silver in an amorphous condition. When chloride of silver without organic matter was reduced by light, it resembled the photographic image, but when treated with hypo it lost something of that appearance, and therefore some persons denied that it was the same substance as that in the fixed photographic image. He had contrived to mix it with gelatine and then reduce it by light, and he thus produced amorphous silver, and this, when treated with hypo, retained its amorphous form. He then mixed it with alcohol and ether, diluted with water, to get it into a thin solution, such as he now held in his hand. It now only remained to analyze it by first weighing

* See a letter from Mr. Brookes on another page.

the amorphous silver, then melting and weighing again, and if it had lost nothing, which he felt assured would be the case, that would make the evidence quite perfect. He concluded by repeating that Mr. Brookes's experiments simply proved nothing beyond the fact that the results produced by light could be produced by other means.

Mr. BROOKES repeated his remark that, according to Dr. Hipson, phosphorescence was induced by the blue ray.

Mr. MALONE said Mr. Brookes was confounding a substance with a phenomenon. Phosphorescence was not phosphorus.

Mr. BROOKES again referred to the bottling up of light, which—

Mr. MALONE reminded him that this had been disproved.

After some further discussion,

Mr. BROOKES expressed an idea that, although phosphorescence and phosphorus were not the same—phosphorescence might become phosphorus.

The CHAIRMAN said Mr. Brookes was evidently confounding two distinct things, and after a few more remarks the subject dropped.

Some further conversation on the alleged photographs of James Watt followed, after which,

The CHAIRMAN said the Chief Baron regretted his inability to be present, but had expressed a wish to meet the Photographic Club and the members of the Society at an annual dinner shortly, when he hoped they would be honoured with the presence of ladies. Before leaving, he recommended members to examine the apparatus kindly brought by Mr. Dallmeyer for their inspection. It appeared to be designed on philosophical principles, and constructed with great care and excellence. The proceedings then terminated.

Photographic Notes and Queries.

BURNING CLIPPINGS OF PRINTS, &c.

SIR,—I have read Mr. England's paper on the recovery of "Photographic Wastes," reported in your valuable NEWS. If you allow me I will tell your readers of an improvement in burning the cuttings and other silvered papers. I take a large flower pot, fill it with the material to be reduced into ashes, and cover it with a large dish, then reverse the whole, so that the dish be underneath, raise a little the pot from it, and in three or four points of its circumference place small stones to admit a draught of air. Set fire to it all round, and the whole will burn thoroughly, the smoke escaping from the hole of the pot, thus not wasting a single particle of the material, either in flames or by wind, the whole having been placed under a chimney to dispose of the unpleasant smell and smoke arising from the combustion.—Yours very obliged,

P. T.

Miscellaneous.

SIR DAVID BREWSTER AND THE STEREOSCOPE.—The *Daily Telegraph*, in recently describing a picture by Mr. Baker, referring to the different figures and their occupation says:—"Sir David Brewster is taking credit to himself for the invention of the stereoscope as a means of demonstrating the theory of binocular vision; while Professors Owen and Faraday are listening, in the absence of Professor Wheatstone, to Sir David's lecture on optics." In answer to this, Sir David writes to the journal in question, stigmatizing the paragraph as a "groundless and malevolent insinuation," and that he had, in 1861, written to the *Times* and to Mr. Baker, saying:—"I think it right to state to you that I am not the discoverer of the stereoscope I am only the inventor of the lenticular stereoscope now in universal use," and adds, "In my 'Treatise on the Stereoscope,' published in 1857, and in various articles on binocular vision of an earlier and a later date, I have endeavoured to discover who were the different inventors of the stereoscope—for every important invention has many claimants—and I have always given Professor Wheatstone the credit of being the first and the only inventor of the reflecting stereoscope.

METRIC WEIGHTS AND MEASURES.—Mr. W. Ewart, chairman of the Select Committee of last year upon the subject, has proposed a Bill for decimalizing our weights and measures, and

making them correspond with those of other countries; and the Bill has on it also the names of three other members of the committee—Mr. Cobden, Mr. Adderley, and Mr. Finlay. The Bill would not come into operation until after three years from its passing. The system proposed would rest upon the metre, which was originally based on the ten-millionth part of the distance from the equator to the pole. The Bill proposes to enact that the unit of the measure of length shall be the new yard, or metre, of thirty-nine inches and 37,079 hundred-thousandths of an inch; that the unit of the measure of surfaces shall be the square of the new yard, except that the square of 100 new yards shall be the unit of land measure, and shall be denominated the new acre, or "hectare;" that the unit of the measure of capacity shall be the new quart, or "litre," the cube of a tenth of the new yard; and that the unit of weight shall be the weight of a new quart of distilled water, to be denominated the "kilogram," the half of which shall be the new pound, consisting of 1 lb. 1 oz., 3 drachms, and 326 thousandths of a drachm avoirdupois. The thousandth part of the kilogram to be called the "gram," and be used in pharmacy and for weighing bullion and precious stones. Tables would be issued by the Board of Trade showing the proportions of these to the old weights and measures. There would be penalties for using the old weights and measures. The Bill is not appointed for second reading until the 1st of July.

PHOTOGRAPHIC PIRACIES AND ITS CONSEQUENCES.—At a recent sitting of the Bankruptcy Court, Mr. Ball applied for his release from custody under the following circumstances. An action had been brought against him by Ernest Gambart, for pirating engravings of the well-known pieces called the "Horse Fair" and the "Light of the World." There was a verdict against him, with £10 damages, but the Court granted a *recurso nisi* for a new trial. The question was argued, and it was finally held that a photographic piracy was within the Copyright Act, whereupon Ball was obliged to come into this court. In his examination he said that a person had told him that Gambart had declared he would "smash him up." The Commissioner said the bankrupt had some reason to suppose he had a good defence to the action, the question as to photographic likenesses being an infringement on the Copyright Act, having never before been decided. There being nothing else against him, he would order his immediate release from custody. In the *Daily Telegraph* of a subsequent day, Mr. Gambart denies the bankrupt's allegation, as to having expressed an intention to "smash him up," saying, "I beg to state that I not only never used such words, but that I know nothing of Ball, except that he has put me to some considerable law expenses. Prosecutions for the infringements of my copyrights are carried on by my solicitors from general instructions to defend my property, without special reference to me, nor animus on my part against the offenders. In the present case I expressed my desire to allow Ball to pass the Bankruptcy Court unopposed, but my solicitor thought it his duty to act otherwise, Ball having declared that he would use his freedom to infringe my copyrights again. . . . I have been put to more than £100 expense, and over half a year's trouble, to get redress against Mr. Ball—and what is the result?"

EFFECTS OF LIGHT ON ANIMAL LIFE.—Light has an undoubted influence on the growth of some of the lower animals. Animalculæ grow, in water, much more readily in the light than in the dark. If equal numbers of silkworms be exposed in a light room and a dark one, many more larvæ will be hatched from the former than the latter. Dr. Edwards found that the development of tadpoles into frogs may be prevented by the absence of light. They only grow into big tadpoles. Several facts tend to the belief that the human body is greatly amenable to the influence of light. Persons living in caves or cellars, or in dark streets, are apt to produce deformed children; and the workers in mines are liable to disease and deformity beyond what could be accounted for by the condition of the atmosphere. It has been affirmed by Sir A. Wylie that, in a large barrack at St. Petersburg, Russia, the cases of disease in those men who have lived on the dark side for many years are three to one compared with those on the light side.

Talk in the Studio.

FLAT BATHS.—We have recently had from Messrs. Bland and Co., some flat baths of excellent form, which for many

purposes are exceedingly convenient and useful. There is a well or reservoir at one end, into which the solution is tilted, whilst the plate is laid flat at the other end. By slightly raising the bath the solution flows in an even wave over the plate, and allows the use of a very small quantity—a point of consideration in using large plates, or in experimental operations. The especial advantage of these we are noticing, consists in the fact that they are sufficiently deep to avoid the risk of spilling the solution in the necessary fillings.

SHEPHERD'S CARD LENSES.—At the conclusion of an article in our last, on Glass-houses, by Mr. Blanchard, he asks our opinion of some prints produced in the studio in question with one of Shepherd's card lenses, as improved by Mr. Squire. The lighting was very satisfactory, and the work of the lens excellent. We have since had an opportunity of trying one of these lenses, received from Mr. Squire. The diameter is $1\frac{3}{4}$ ths of an inch, the back focus is a little under five inches, and the equivalent focus about six inches. For card portraits its action is very satisfactory, defining well with a moderately large aperture, and working quickly. In the Waterhouse diaphragms, an ingenious method is adopted, which allows the outer tube or jacket to travel over the stop, instead of having a large slot in the tube as is usual. This prevents light entering when no stop is used; but it has the disadvantage of not permitting a change of stops without altering the focus.

ENAMELLED PAPERS.—We have received from the Hon. Nassau Jocelyn some further beautiful specimens of enamelled paper, and also of another photographic paper, of which we shall have more to say. We learn that this paper is prepared by M. Beyrich, of Berlin, and that Mr. C. Trubner, of St. Dunstan's Hill, is the London agent. We have also received further samples of Schering's paper from Mr. Spencer, which show decidedly an improvement in preparation. The finest prints we have yet seen on enamelled paper are some sent to us by Messrs. Harvey, Reynolds, and Fowler, on paper for which they are agents, but prepared by whom, is not stated. The prints are exquisitely delicate and brilliant. We have also received from Mr. Cooper some samples of enamelled paper without albumen. We have only made a hasty trial, but are much surprised at the results. The tone is black in the printing frame, and remains so when fixed in hypo without having been toned in any way whatever. We shall be able to give further particulars of Mr. Cooper's experience and our own shortly.

To Correspondents.

MR. CLARK ON "PHOTOGRAPHY AS A FINE ART," &c.—We have received three or four communications on Mr. Clark's recent papers before the Scottish Society. His rapid platitudes on the art-claims of photography are more than answered in the communications of R. A. S. and Mr. Fry, which appear on another page. On the splenetic part of his communications, another correspondent, H. L. Snowden, writes: "Who is this Sir Oracle who lays down the canons of criticism and good taste with such self-satisfied egotism? He appears to have digested the venom of his spleen till it hath split him! Some of the critics seem some long time ago to have pinched him, and he has had no opportunity of squeaking until now; but what has Mr. Shadbolt done lately to be so indecently bespattered with bad language?" We know nothing of Mr. Clark except that he has produced some good photographs and two foolish papers. The cause of the last attack to which you refer appears to be this: At a conversation at Glasgow, Mr. Mactear read a paper which some time ago appeared in the *Photographic News*, having been contributed by Mr. Mudd. This we are sure was done without the slightest intention of plagiarism, or we might have felt aggrieved, and have noticed the matter. In the report of the meeting, as given in a contemporary, it unfortunately appeared as if Mr. Mactear had read this as an original composition, and Mr. Mudd very naturally reclaimed his own paper. His letter, making this reclamation, received from the Editor of our contemporary the unfortunate heading which has aroused Mr. Clark's ire. We are not called upon to discuss the good taste of the heading; but it is evident to the commonest capacity that nothing offensive was intended by it; whilst anything more offensive to good taste than Mr. Clark's unqualified charges of "gross impudence," &c., in a matter which did not concern him, and in which he had no right to intermeddle, we have not often met with. If it be intended as a defence of his friend, Mr. Mudd may well exclaim, "Save me from my friends!" As for the photographic press, it can well afford to smile at Mr. Clark's estimate of it. Mr. Clark, we believe, resides in Manchester, or near it, but we fear he has not paid the "extra threepence to learn manners."

B. B.—Your cards indicate the presence of too much top and front light. We do not quite understand the sketch of your room, but it will be almost impossible to get universally good effects without blinds. As a general rule a strong light favours density of the negative; but yours are not lacking in this respect. Your prints are mealy. Either use the acetate bath, or let your solution be made a little longer before using it.

HYP.—There is a considerable improvement in your cards, especially in

the lighting. Some are very good indeed. A little bromide added to your collodion would enable you to work cleaner, and to get rid of the tendency to little spots present in some cases. There is a slight degree of under-exposure in some of the pictures.

A POOR AMATEUR.—In testing a lens in the open air upon a restless child with flowers, agitated by the wind just in front, you certainly did not give the lens any chance. The moving flowers and restless child were not sharp, but a thorn-bush behind the child was sharp, because it did not move. Try the lens again on some still life object. Make a pile of books, or several piles, arranged so as to secure several planes of distance, and focus for one midway between the most advanced and most retired. If you then find a discrepancy between the chemical and visual foci, examine the camera carefully, and measure to see that the distance between the lens and ground glass is exactly the same as between the lens and the sensitive plate. As to the price, it appears you got it cheap.

W. S.—We should think that with a room of 21 feet long you could work the No. 2 B of the maker you name. The same lens is made with a focus a trifle shorter, we believe, for shorter rooms. It is preferable to the No. 1 B of the same maker, as being more rapid, covering better, and for the same sized picture giving more modelling and depth of focus. But we have seen very excellent results with the latter.

SRILL.—We fear you would find it somewhat difficult to construct the apparatus merely from a description; but we will endeavour to find space for further particulars shortly.

YOUNG AMATEUR.—About 23 inches is the proper distance from centre to centre of the stereo slide. If your negatives are $\frac{3}{4}$ apart, the lenses in the copying camera must be a little closer together. You will find it very desirable to have a lateral adjustment to enable you to alter the position, a little, of the lenses. Transparencies taken with a bi-lens copying camera from negatives taken with a bi-lens camera do not need cutting or reversing, as the process of camera copying turns each picture round on its axis, and produces the proper result in that way.

PHOTOGRAPHER.—The propriety of adding water to the acids in making gun-cotton entirely depends upon the strength of the acids, the temperature, and the result desired. We prefer equal proportions of nitric acid at 1-420 and commercial oil of vitriol, used at a temperature of 150° Fah. See our *ALMANAC* and various articles in our pages.

CHARLES ROWLAND.—The chief faults in your pictures arise from under-exposure, and you have too much top light. You will also get more softness and cleanliness by using a collodion with more bromide. If you send us a directed envelope we can give you the address of a capable teacher.

A.—Nitric is not the best flux for the ashes of silvered paper. Read Mr. England's paper in our number for May 15th. You probably did not use sufficient heat, and your crucible must have cracked or have been imperfect. You probably used an unsuitable collodion for your Fothergill plate, but your details are scarcely explicit enough to enable us to form an opinion.

X. X. X.—So far as we can judge, a very respectable glass-house may be made on the plan forwarded. Judging from the plan, we should decidedly place the siter at A, if placed at B there will be too much front light.

J. L.—With a single lens of 12 inches focus the largest stop we should recommend you ever to use is that of one-inch aperture. If the five-eighths of an inch stop is the smallest you have, use it wherever the light will permit you. The exposure required depends upon so many things, such as the state of the chemicals, the kind of object, and the distance it is from the camera, the condition of light, &c., that it is impossible to state it with any accuracy. In a good light, with the stop of one inch, try about ten or fifteen seconds, and with the five-eighths stop three or four times that exposure. 2. Mr. Window has used simply washed plates, with and without a final immersion in gallic acid, in both cases with good results; but with the best when using the gallic acid. The lens he used in testing the plate: was one of Dallmeyer's new stereo lenses of four and four-tenths equivalent focus. The aperture we are not certain about.

E. AND J. LANCASTER send us a photograph with a very singular defect. It is granular and mealy-looking to an extent which destroys modelling and sharpness, having much the effect of a coarse lithograph. The defect, they state, is owing to the character of the negative, which presents the same granular appearance. We should suspect the cause to be under-exposure, and pushing in development with a plentiful supply of silver, possibly taken from the nitrate bath, which, being thrown down rapidly in coarse particles, thus destroys sharpness, and gives the coarse blurred effect. Several Correspondents in our next.

FORMIC ACID AS AN ACCELERATOR.

A SINGULAR discrepancy of opinion and experience seems to prevail regarding the use of formic acid in the developer. The first record we have of its use appeared some ten years ago in the Society's journal, when it was proposed by the Rev. J. Lawson Sisson, for addition to the protonitrate developer, to secure good tones in collodion positives. We tried it about that time, for that purpose, without perceiving any advantage. Since then its use has occasionally been suggested from time to time. About a couple of years ago considerable discussion was caused by a somewhat indefinite allusion to its use as an aid to instantaneous photography. by MM. Ferrier and Soulier, some charming stereoscopic street scenes of Paris having been, it was stated, produced by its aid. The matter was, however, very ambiguously stated, and the photographic public were not much enlightened at the time. Shortly afterwards a communication appeared in our columns from Col. Stuart Wortley, who gave a definite formula for the use of formic acid with iron, and spoke in high terms of its value. His large instantaneous pictures produced by its aid were strongly corroborative of the statement. It was urged, however, by some that the brilliant light of Italy might have produced the results without the formic acid affecting the matter. In the course of last summer a group of two figures, portraits of the Secretaries to the English and French Photographic Societies, on a 12 by 10 plate, was exhibited in the International Exhibition. The negative of this picture, which was delicate, soft, and perfectly exposed, was produced in the studio of M. Claudet with a lens of long focus and small aperture in a very dull light, with an exposure of nine seconds. Mr. H. Claudet communicated to us the process by which this unusual rapidity was obtained, claiming for formic acid the accelerating properties. Since the publication of this communication in our own and some other journals, a more extended discussion of the subject has arisen. Many experimentalists have tried formic acid in the developer, and with, as we have said, singularly discrepant results. Amongst those who have derived no advantage from its use is Dr. Van Monckhoven, a good authority, both as chemist and photographer. Several other photographers, upon whose opinion we could place reliance, have found similar results, and made similar reports. Our own engagements have precluded hitherto a careful and systematic examination of the subject.

A few days ago we went, at the courteous invitation of M. H. Claudet, to his studio in Regent Street, for the purpose of witnessing his operations and verifying the results of formic acid in his hands. We must confess at the outset we were altogether unprepared for the amazing rapidity we witnessed. We will simply and briefly state the details of what we saw. M. Claudet's admirably appointed studio is, like many studios in London, somewhat unfortunately placed as regards light, the best light being cut off by a dark brick building which rises high above the studio, so that it

is to a large extent, as M. Claudet phrased it, in a well. Added to this, the sun shines directly into the room at mid-day, rendering it imperative to use a large surface of blinds. The lenses used for card portraits are of long focus by Voigtlander; the equivalent focus was $9\frac{1}{2}$ inches, the diameter of the lenses $2\frac{3}{4}$ inches. We stood for a negative about mid-day, surrounded by blinds to shut out the direct sunlight. So far as we can judge without direct comparison, an exposure of ten seconds would have been requisite with good bromo-iodized collodion and an iron developer. To our unbounded surprise the lens was closed with exposure of barely two seconds. We then went into the dark room to watch the development. The image flashed out rapidly and in less than a minute was completely developed, the result being clean and brilliant without the slightest trace of fog. Another plate was now prepared, and the sun having retired behind some grey clouds, a portion of the blinds were withdrawn. The exposure this time was one second, and the results in the dark room similar. Perhaps the negative might have borne the fraction of a second longer exposure, but certainly not another second. We unhesitatingly affirm that we have not seen at any time such rapid working in a studio in so dull a light.

The materials were, for the most part, such as M. H. Claudet described on a former occasion, but we may describe them again here. The nitrate bath contains—

Nitrate of silver (commercial) ...	700 grains
Strong nitric acid	3 drops
Distilled water	1 pint

prepared in the usual manner.

This works better when first used, a slight deterioration in sensitiveness being observed after it has been used a short time. When this becomes too definitely marked the bath is laid aside and thrown down.

The collodion used is simply iodized, and contains equal portions of cadmium and potassium. A stock of Thomas's ready iodized cadmium collodion is kept on hand. The ordinary negative collodion of the same maker, with the potassium of salt, is iodized about ten days before it is required for use. Equal portions of these two collodions are then mixed for use.

The developer we saw used was prepared as follows:—

Pyrogallic acid	20 grains
Formic acid (Morson's)	1 ounce
Water	$7\frac{1}{2}$ "

Alcohol, *quantum suff.*

The points upon which M. Claudet laid especial stress were care and exactitude in the formula generally. Regarding the formic acid the exact degree of purity and strength are not yet satisfactorily determined, and the proportion to be used has to be decided at present somewhat empirically by actual experiment with each fresh stock. The proportions given answer with the sample in hand. Of another sample, prepared by Mr. Hockin, of alleged absolute purity, one-fourth of the proportion given in the formula was sufficient.

It is stated to be important, however, that the right proportion of any sample should be ascertained, as with an insufficient quantity the benefits are not attained, and with excess the result is tardiness in developing and fog. It is important to use as little light as can conveniently be worked with in the dark room, or fog may ensue. And it is important to drain the plate very carefully as excess of free nitrate is apt to cause surface reduction. It will, moreover, be very evident that in proportion to the rapidity of a process, is its delicacy and sensitiveness to all causes of abnormal reduction. Clean plates, filtered solutions, and great care in all the manipulating, as well as accurate timing, is of the utmost importance.

Such are the results of our observation in M. Claudet's studio. We have made a few experiments ourselves, but they are insufficient for comparative purposes. We may, however, briefly refer to them. With a developer made after Mr. Claudet's formula, but with half the proportion of formic acid, a sample supplied by Messrs. Hopkin and Williams, we obtained with iodized collodion similar results to those yielded by iron and the same collodion with a bromide. With the same developer and a bromo-iodized collodion, the results were similar to those obtained with iron and with the same exposure. The chief action of a bromide with the pyrogallic acid and formic acid appears to be to give greater delicacy of image, but the exposure was about the same. As, however, it appears probable that much of the advantage of the formic acid depends upon a strict exactitude of conditions which we have not yet applied, we refrain from further reference to our own experiments.

We may here call attention to the detail of some interesting experiments in the same direction by Mr. Cooper, which will be found on another page, from which it will be deduced that more is still to be learnt as to the exact operation of this acid in the developer.

BROMIDE IN POTASSIUM IODIZED COLLODION.

Iodide of potassium, at one time a favourite iodizer for collodion, has of late years, since the more extended employment of bromides, fallen considerably into disuse. Whilst less stable in sensitiveness, the collodion containing this salt unquestionably favoured density and brilliancy in the image. For this quality many photographers would gladly have continued its use, if it could have been conveniently done in conjunction with a bromide: its rejection having been rather the result of necessity than choice. The bromide most commonly used has been the bromide of cadmium, which has been selected chiefly on account of its ready solubility in alcohol. But when this bromide is used in conjunction with the iodide of potassium, a double decomposition often ensues, forming bromide of potassium and iodide of cadmium. As the bromide of potassium is very sparingly soluble in the mixture of ether and alcohol employed in collodion, it is thrown down and its advantage is lost. Hence the use of iodide of potassium has fallen into disfavour.

We have recently found a method of using this salt in combination with any amount of bromide we may desire to add to the collodion. It consists in the employment of bromide of lithium in conjunction with the potassium salt. This bromide is much more stable than that of cadmium, and is also very soluble, may be used freely in conjunction with the iodide of potassium without any decomposition. The result is a collodion yielding very vigorous, clean, and brilliant negatives. To add to these qualities that of stability, it will probably be desirable to use a portion of iodide of cadmium. A collodion giving great brilliancy and delicacy, and with every probability of stability, will stand thus:—

Ether, 720 sp. gr.	1 ounce
Alcohol, 715 sp. gr.	1 "
Iodide of cadmium	5 grains
" potassium	4 "
Bromide of lithium	3 "
Gun cotton, <i>quantum suff.</i>			

Scientific Gossip.

MEASUREMENT OF THE CHEMICAL ACTION OF LIGHT—NEW SPECTROSCOPE—EXAMINATION OF GLASS.

THE measurement of the chemical action of sunlight has been a problem which has engaged the attention of men of science for many years. Under the names of Actinometer, Dynactinometer, Photographometer, &c., various instruments have been devised for measuring and recording the variations of the actinic or chemical force of the solar ray; but in spite of all the attempts which have been made in this direction, a good instrument of this kind, of easy use in observation, is still a desideratum. The subject formed the Friday evening discourse at the Royal Institution, on the 22nd ult., the lecturer being Prof. Roscoe, a physicist who has long studied the subject from a scientific as well as practical point of view, in conjunction with Professor Bunsen, of Heidelberg. The lecturer began by stating that animal life might be considered as a process of oxidation—the tissues of the body undergoing combustion in the oxygen of the atmosphere, and forming carbonic acid. Without some counteracting agency, an animal, so long as it breathed, might be said to be slowly working its own destruction by forming a gas incapable of supporting life. The counteracting agency nature supplied in the life of plants, which might be described as the opposite process of reduction, carbonic acid being decomposed and oxygen evolved. Animal force, then, was derived from the vegetable organism, and animals did not create but only manifested force, which was regulated by the same law as that of the steam engine, the force representing exactly the amount of fuel consumed. For vegetable life a continual stimulus was necessary, and this was supplied by the sun, the chemical radiations of which brought about the decomposition of carbonic acid by plants in the same way as they decomposed chloride of silver on photographic paper, and caused the combination of hydrogen and chlorine. That all the rays of light were not of equal chemical activity the lecturer showed by exposing a thin glass bulb filled with a mixture of hydrogen and chlorine, first to red light and then to violet light. In the former case no alteration was effected, whilst in the latter case an explosion took place which shattered the globe to pieces. The experiments, which were most effective, were made by burning phosphorus in oxygen gas contained in a globe of red or violet coloured glass.

The measurement of the chemical activity of solar light, the lecturer continued, was a subject of great importance and interest, inasmuch as it afforded a means of estimating the vegetable and consequently the animal producing power of a country or district. He had therefore made experiments with a view to obtain an easy and exact method of measuring the chemical action exerted by the total sunlight at any point of the earth's surface, under the different conditions of situation, climate, and state of atmosphere. It was known that the real climate of two countries might differ very widely, and yet the mean temperature of the two be nearly the same. This was shown by the vegetation of the two. To illustrate this, the lecturer exhibited photographic views taken near Carlisle, and in one of the Shetland islands—the mean temperature of these two localities being nearly the same. The vegetation about Carlisle, however, was luxuriant, while not a tree was to be seen in the Shetland views. These differences were owing to the different intensity of the chemical action of light, and not to temperature. The foggy, cloudy atmosphere of the Shetlands absorbed the chemical rays which would stimulate vegetation. It was of consequence, therefore, to have a means of determining the chemical activity of light, the measurement of which would create a new and important branch of meteorological science. In conjunction with Professor Bunsen, the lecturer had some years ago constructed a chemical photometer, for estimating the chemical activity of light, by its

effect on a mixture of hydrogen and chlorine. This instrument, however, was too complicated to be available for meteorological purposes. Another and simpler way of measuring the activity of diffused or direct light on any given spot was necessary, and the mode proposed was the registration of the result produced on photographic paper. But before such a mode could be made available, it was necessary to know how to obtain photographic paper of constant sensitiveness, and also what relation there existed between the degree of tint produced and the time and intensity of light necessary to produce it. After a series of experiments, the lecturer had succeeded in preparing a paper of constant sensitiveness, and in the method which he proposed to have adopted, the comparisons were not made between the different tints of the papers, but between the different amounts of light which were radiated by the variously-darkened surfaces. The method was founded on direct observation. It was possible to measure the time required to produce a given tint on standard paper, and the intensity which produces this tint in the unit of time is called the unit of chemical intensity. If two units of time are necessary, the intensity will be one-half, and so on. The time of insolation is measured by means of a pendulum photometer, in which the strip of prepared paper is exposed for a varying but exactly known time. By the action of the pendulum, a piece of blackened mica is passed and re-passed over the paper. Different parts of the paper are necessarily exposed, for different lengths of time, but the time of exposure of any part can be calculated exactly from a scale. The strips of paper thus insolated exhibit a regularly diminishing shade from black to white, and the point at which the paper has a shade equal to a normal tint, fixed by means of hyposulphite of soda, can be accurately read by comparing the two strips, by the aid of monochromatic soda light. In illustration of this the lecturer showed the effects of the sodium flame on the words "monochromatic light," printed in letters of various colours, and also the way in which the exposed papers were compared; but it would be impossible to make the latter intelligible, unless the apparatus were before the reader. The experiments by Professor Roscoe and another observer at Manchester have shown that two experimenters may closely agree in their estimations of tints by this means. The lecturer then briefly referred to some measurements he had made of the chemical brightness of various points of the sun's surface. From these it appeared that the chemical brightness of different parts of the sun's disc is very different, the central portion being from three to five times brighter than portions of the edge. He had found, too, that the brightness of the picture varied irregularly; a coarse, mottled appearance being produced, very different from the ordinary mottling seen on the surface of the sun. He had satisfied himself that this appearance was not due either to the paper or the lens, and he thought it probably arose from clouds in the sun's atmosphere, and might be connected with the red prominences seen in eclipses. The professor remarked in conclusion that he was convinced that interesting and valuable results might be obtained by the methodical carrying out of actino-meteorological observations, such as he had described, and he looked forward to the time when all meteorological observatories would be furnished with instruments for pursuing it.

Those of our readers who possess spectrum apparatus may be interested in knowing of a plan which has just been devised by which all the benefits of a large instrument are obtained with half the number of prisms and lenses. In the ordinary instrument the ray of light passing in at the slit goes through the collimator and train of prisms to the telescope, and thence through the eyepiece to the observer. The improvement, which is due to M. O. de Littrow, consists in allowing the ray of light to pass through the slit, collimator, and prisms as in the old arrangement. It then falls perpendicularly upon a plane mirror and is reflected back through all the prisms a second time. It then passes through

the collimator, and, if not arrested, would proceed to the slit again. But the collimating lens is identically the same as the object glass of the telescope, so it is only necessary to interpose a plane reflector in the path of the return rays between the collimator and slit, to deflect them sideways through an eyepiece where the spectrum is examined. By this arrangement one lens is dispensed with and a double effect is obtained by the same number of prisms; moreover, the proximity of the eyepiece to the slit facilitates manipulation.

A correspondent, H. G., has forwarded a piece of glass for spectroscopic examination. In the instrument it is seen to cut off all the chemically active rays down to the green; it may therefore be used with perfect safety. The colour is deep orange: it is flashed with silver.

FORMIC ACID IN THE DEVELOPER.

BY H. COOPER, JUNR.*

A FEW weeks back I sent to the photographic journals a *resumé* of some experiments with formic acid in the developer as an adjunct to great rapidity in working the wet collodion process. (I have not as yet tried it with the dry processes, but hope to do so during the ensuing summer). I have since continued my experiments and have arrived at some very curious results, a few of which I shall have the pleasure of showing you this evening. I have brought very few examples with me as I think it is better to exhibit a small number that clearly show the different results obtained, than to perplex you with a great many that only confuse, and lead to no correct opinion being formed.

My first series of experiments were devoted to the attention of iron as a developer; but when I wrote the letter to which I referred, I had not used for trial the double sulphate of iron and ammonia. With this salt, employed as usual, I am much pleased, as it is much easier to work and therefore more pleasant than the ordinary sulphate. I am also of opinion that it requires rather less exposure in the camera. From this I was naturally led to expect that the reduction in the time of exposure would be still greater if it were employed with formic acid. I was rather disappointed with the results which showed that little or no increase of rapidity is gained; but on the whole I think a more delicate negative is procured.

I ought to have mentioned in what manner my experiments were conducted; for if the plates are not exposed simultaneously, no definite conclusion can be arrived at. Much unnecessary discussion has arisen through carelessness or neglect of this precaution. I had several stereoscopic glasses cut across the centre with a diamond, so that, after exposing the plate by the means of a pair of stereoscopic lenses, it may be broken and the two halves developed in different ways. It is also requisite that the lenses be fitted with some contrivance for uncovering them at the same instant.

During the past week I have turned my attention to formic acid, used with pyrogallic acid, and it was during these experiments that some most curious anomalies presented themselves.

The first plate (which I now produce) I exposed during a very weak and muggy light. You will observe that the half developed with pyro and formic acid is clean and brilliant, though under-exposed, and that the other half, developed with the ordinary solution of 15 grains of sulphate of iron and 15 minims of acetic acid to the ounce of water, is much stained, and that only a mere trace of an image is visible. I immediately exposed another plate with the same result. I purposely gave them all less exposure than I should if I had intended to develop them in the ordinary way.

I then waited till the light had become very bright, and exposed another plate, which I bring with me, in which the

* Read at a meeting of the South London Society, June 11th.

part developed with pyro, as before, appears considerably less exposed than the one developed with iron.

From repeated experiments which have given analogous results, I have formed the following conclusions:—First, That under certain conditions formic acid is a decided accelerator in *any* developer; for instance, when the light is so weak that sulphate of iron will not allow the development to be pushed sufficiently without staining the negative; formic acid, under these circumstances, produces, as I have observed, a striking improvement. Secondly, But that in a good, strong light, the usual developer of iron requires less exposure to produce a satisfactory result than pyro and formic; and that formic acid and iron, with a little acetic acid, is quicker than all. In making these remarks I wish you to understand that all the chemicals used are in good working condition.

DEVELOPING AND INTENSIFYING.

BY J. C. LEAKE, JUN.*

PERHAPS no term is more often misapplied than this one, intensity. I am not quite sure if I know its meaning myself; but I think, as applied photographically, it means that quality which will enable the negative to reproduce on paper an impression of the original subject photographed in its correct light and state.

This being granted, we will proceed to examine the various processes used to this end.

One error seems to me prevails largely among photographers on this subject; it is this, that the same amount of brilliancy is necessary in all their productions. Now I venture to suggest that this is wrong, and, that while for many, perhaps most subjects, the more brilliant the lights and the deeper the darks, the better; yet in some cases it will be advisable to diminish the intensity in order to produce a softer and more artistic effect.

I make these remarks, because as we proceed, you will find I lay down no definite rule as to intensity, but endeavour to explain the tendency of each process named, leaving the application to individual judgment.

Some years since, when a simply iodized collodion was used, the impression being developed by pyrogallie acid, no difficulty was experienced as to getting a full amount of intensity. But the introduction of bromides, and iron development made so marked a difference in the beauty of gradation and the capacity with which pictures could be produced, that notwithstanding it was often found difficult to get sufficient density for printing purposes, the process has come into general use.

I am not of those, however, who think the image on bromo-iodized collodion developer with iron, is necessarily thin. On the contrary, I believe that, with proper care, an impression may be obtained of sufficient density to print at once without any intensification whatever, although I do not think it judicious as a rule.

If we start by examining the conditions likely to affect the intensity of the image, we shall perhaps be better able to understand the subject.

To begin with the collodion; of course, bromo-iodized. The best results will undoubtedly be obtained when it has been iodized at least a week. If the image is thin (as it would be if the collodion were used immediately after iodizing), it cannot readily be brought up to the required strength. It is well to have a good full film, or it will be difficult to obtain a rich, deep negative. But most important of all is the condition of the silver bath. I may as well at once confess to heresy on this point; for notwithstanding all that has been said and written to the contrary, my opinion still is, that the presence of an acetate is of the utmost use, both as to rapidity of action, density, and colour of the deposit. The presence of uric acid, often recommended to be added to the bath, has a tendency to produce

a grey metallic deposit, which is next to useless for printing, and very difficult to intensify. If carbonate of soda be added to the nitrate solution, and left in contact with it some hours, it will be found that the image, which before was grey and transparent, is now of a rich brown, much more intense, and capable of being intensified to almost any extent. As might have been anticipated, the length of exposure affects the intensity to a large extent, and it will be found that the best results will be obtained when the exposure has been so prolonged that one application of the developer is sufficient to thoroughly bring out the impression.

From time to time various substances have been recommended as likely to increase the density of the image when used in conjunction with the ordinary sulphate of iron developer. After trying a number of experiments, however, I am inclined to think that, as a general rule, a developing solution containing from ten to twenty grains of iron, and the same proportion of acetic acid, will be found to answer for general purposes better than one made according to more complicated formula.

At this stage of the process the image should present the following characteristics,—all the details should be well out, the high lights sharp, while in the deepest part of the shadows the iodide should remain unaltered in colour, the whole picture standing out boldly and having a generally "plucky" appearance.

I am convinced that a great deal of time and trouble is wasted, and many failures incurred (the blame being thrown on the process employed), in trying to intensify pictures which cannot by any process be made to yield a respectable print by reason of their infirmity; and the unfortunate man who has suggested a process for intensifying which answers well in his hands, is consigned to various places as a "muff," because that same process will not convert anything anybody may happen to get into a first-rate printing negative, without any trouble whatever.

So that while I cheerfully admit that "dodges" may be useful at times, the best "dodge" will be to endeavour to secure a picture which will require as small an amount of after treatment as possible. There now remains three stages during which the negative may be intensified—before the removal of the unaltered iodide by the fixing agent, after the fixing process, and also after the film is dry. Intensifying, at each of these stages produces a slightly different result. The softest negatives are, as a rule, produced by using a weak solution of pyrogallie acid and silver before fixing; but it should be remembered that unless very carefully used this process is likely to obscure the delicate detail of the negative by a heavy deposit of silver. If, however, the iodide be removed by fixing, this process with pyrogallie acid is perhaps the safest and most certain now in use, and, doubtless, in good hands is capable of producing the most beautiful results. For my own part, I am inclined to think these two methods may be used in conjunction most advantageously, a little being done before, and some after, fixing. If the original negative be very thin it will often be found difficult to obtain the requisite density for printing after fixing; but if we intensify slightly before, we shall have but little trouble afterwards in obtaining any reasonable quantity. Before the iodide is removed the intensity seems to be obtained by an actual deposit of silver, but after its removal scarcely any silver appears to be deposited, but the colour of the negative is altered from grey to a rich non-actinic brown. Greatly favouring, as I do, the idea that intensity by colour is better than intensity by deposit, I think that if a fair amount of deposit can be obtained by iron, and this slightly altered in colour by the after application of the pyrogallie solution after fixing, better and more delicate negatives may be produced by this than by any other process; but it must be borne in mind that an increased tendency to hardness accompanies all processes used for intensifying *after* fixing. It may not be out of place to mention here that, when it is intended to use this process, the hypo-

* Read at a meeting of the London Photographic Society, June 11th.

sulphite of soda will be found the best fixing agent; while for the others to be mentioned cyanide is to be preferred, as leaving the deposit in a better condition for the after applications.

The ordinary sulphate of iron developer, with the addition of citric acid, has been recommended as a convenient intensifier. That it is clean, and works evenly and steadily, cannot be denied, but I think it is objectionable on account of the colour it produces—grey. It is, in fact, density by deposit instead of by colour, and is therefore to be avoided. The application of a solution of iodine to the film before intensifying with pyrogallie acid has also been advised, and, where the original deposit is very thin, is undoubtedly useful, the more so as it slightly changes the colour.

The only important process now remaining to be discussed is that with bichloride of mercury and iodide of potassium. This comes into the third stage mentioned at starting; as to do any good the film must have been dried before the application of the solutions. As a preliminary remark, I may say that it is judicious to varnish the edges of the plates to be operated on by this process, before the solutions are applied.

The fact of having made a few hundreds of experiments tends to give me boldness when speaking of this process, and I have no hesitation in offering my opinion that in careful hands it is capable of producing better results than any other; but I cannot recommend it for general use for various reasons. In the first place, if the exposure be not right to a second, no care or "dodging" will make a fine negative; and we all know—at least, all engaged professionally—that we cannot always take a second picture, while some irascible old gentleman, who wants to catch the "next train," is waiting to sit, and working himself into a state "better imagined than described," by way of securing a pleasant expression. Then the printing from the negative requires extra care, another commodity, by the way, not always obtainable—and so on throughout.

But, if prepared to give unlimited care, time, and attention to every part of the work, by all means use this process for the production of your negatives. Perhaps the most usual cause of failure in this process is the use of too strong a solution of bichloride of mercury. If, instead of a saturated solution, as usually recommended, we use one of from half a grain to a grain to the ounce of water, far better results will be obtained, and much of the unequal action so often complained of be avoided. The iodide of potassium solution of five grains to the ounce of water will be found to answer perfectly. It is a point of vital importance to the success of this process that there should be no deposit whatever on the deepest shadows. For the other methods named, this may not be so important, although it is best at all times, but it will be found useless to attempt to intensify by this method anything but the most brilliant and perfect pictures. Too great a heat should not be applied to pictures produced by this process while varnishing them, as some varnishes very readily dissolve the thin deposit of iodide of mercury formed upon the surface of the plate, leaving it in precisely the same condition as before intensifying.

Chloride of gold has been recommended as an intensifying agent; but, beyond the objection of expense, it has that of being almost useless. Hyposulphite of soda, in conjunction with bichloride of mercury, has been spoken of as useful, as also hydrosulphate of ammonia; but, on the whole, none of these substances can be favourably spoken of, the last being specially objectionable. A somewhat dangerous, yet a useful "dodge," when a negative is slightly over-exposed, is to pour over it a weak solution of iodine, and then, after thorough washing, a weak solution of cyanide of potassium, repeating the process until some one or two portions of the deepest shadows are reduced to bare glass. For positives this answers capitally, if carefully executed; and, although I do not recommend it, a negative may frequently be saved by its adoption. Of course, after this treatment, the negative must be intensified by one of the before-mentioned

processes—that with the bichloride of mercury having, in my hauds, answered best.

In concluding what I fear has been a very tedious paper, I would observe that in aiming, as we all do, at the production of brilliant and perfect proofs, it must be kept in mind that all the parts of the process depend one on the other, and that perfection will only be attained when they are perfectly related one to the other. We are frequently astonished to hear of the most exquisite results being produced by means of a process which we thought incapable of producing them, and, on inquiry we find that the secret is simply this: the great care bestowed in arranging all the details, in order that one may work into the other.

Then the importance of the arrangement of light on the model cannot be over estimated, lying, as it does, at the root of the question of intensity; and it will be useless to work up processes for the production of perfect negatives, unless proper attention be paid to this. I had intended to commence this paper with some remarks bearing on this part of the subject, but, having a wholesome fear of Mr. Wall before me, I determined to leave that to him; as I do also the responsibility which might attach itself to me on account of having taken up your time this evening, for had it not been for his kindness in dragging me out on account of a few remarks which I made to him at the last meeting, I should not have ventured to occupy your valuable time this evening.

I regret that through pressure of business I am unable to make this paper more perfect. Many experiments intended I have been unable to perform; but I have laid before you what is done, in the hope of resuming the subject at a future time.

ART IN PHOTOGRAPHY.

BY M. BLANQUART EVRARD.

WE know how little is due to art in the production of a photographic negative. The selection of the subject, the lighting of the model, and the pose, when it is a living subject. This is but little, yet it is all to which the influence of art is reduced; and still, little as it is, it is easy to recognise it in the pictures of operators who have a true perception and feeling for art, while we often have to regret its absence in those operators who owe all their success to science and skill in manipulation.

Thus amid the magnificent progress imparted daily by science to photography, how much regret we experience that art remains as it was at its *début*—powerless to modify, by taste or feeling, the picture proceeding from the Daguerrian camera. Let us conceive what a transformation photography would undergo if the operator would but regard the picture drawn in the camera by light only as a beautiful, faithful sketch waiting artistic inspiration to be completed. It would be like those rare engravings which, beside faithfully reproducing the work of the painter, bear also the impress of the individual feeling of the engraver, and render the copy superior to the original. The problem to be solved will then be to limit the marvellous but intelligent work of the camera to the complete but not intense formation of the image, and giving the photographer the means of continuing it, and modifying at will the aspect and accessories, and substituting, so to speak, his action for that of the camera, and employing the same chemical means of execution. It is not a galvanic action like that we were the first to indicate in 1851, and which consists in precipitating by means of a metallic bath upon the image ready formed, but recognised as too weak, a fresh quantity of metal to strengthen it: This process, in daily use, can, fortunately, be performed only upon the whole surface of the negative; its result does not solve our problem as it does not modify the effects of the picture, it only changes the scale. Nor will it consist of the re-touches which a skilful hand is sometimes obliged to add to a negative. What pencil is skilful enough to combine its work with that performed by the luminous rays? and yet

the result we must obtain should be the power of strengthening this or that portion of a picture at pleasure:

The artistic work of which we speak in this place can be produced neither by pencil nor palette, it must remain purely chemical, so as not to alter the purity of the lines, and have the picture in a perfectly homogeneous condition, with all its finish and delicacy of execution. We must discover an agent so subtle as to be able to rival light, or, still better, have recourse to light itself. The problem to be solved will therefore assume the following form:—

Bring the light to continue, and to modify in its effect, at the will of the operator, the image formed in the camera.

When a layer of iodized collodion is moistened with a solution of nitrate of silver, there is an exchange of bases, and formation of iodide of silver with excess of silver: This is what in practice we term the sensitive film.

Exposing the sensitive film in the camera, all the points more or less luminous of the image act upon the sensitive film in proportion to their intensity, and a complete image is formed, but invisible after an ordinary exposure.

It might be thought that this image would be visible by transmitted light, but nothing is visible to the naked eye. It is necessary for the latent image to be revealed, to be submitted to the action of one of the three developing agents usually employed—gallic acid, pyrogallic acid, or sulphate of iron. The picture then manifests itself under the form of a metallic precipitate, weak in those parts where the action of the light has been feeble, abundant where it has been intense. It is from this variety of transparency or opacity in the parts of the image that results that beautiful gradation of light and shade which forms the charm of successful pictures.

The abundance of the precipitate produced by the action of the reducing salt upon the portions of silver impressed by the light is therefore proportional to the intensity of that impression. If the image is deficient in opacity on account of the precipitate being too weak, it shows that the luminous action has been insufficient. We must in that case submit the negative to a fresh exposure in the camera. But this result, good in theory, has no practical value, and only in very rare cases can we resume the pose of a model, under conditions precisely identical; and, moreover, if the thing were easy, we should only possess a new method of strengthening, which is not the object of our inquiry.

It would be entirely different if we could succeed in isolating the image from its medium, or, in other words, if we could preserve to the elements of which it is composed, their photogenic properties, and render insensible to a new exposure the metal, which, not having been impressed at first, remains useless to the formation of the picture.

To arrive at the solution of this interesting problem, let us first study the conditions of the formation of the picture upon the collodion negative.

Contrary to what takes place upon a paper negative, where the image is deeply impressed in the whole texture of the paper, the picture of a collodion negative is formed only by the reduction of silver precipitated in the state of a metallic powder, without cohesion, upon the collodion film, from whence it is removed upon the least contact, without leaving any trace of the image.

Evidently the reductions arise only from the salts of silver in excess in the formation of iodide of silver.

For, if by washing in abundant water we remove from the sensitized collodion the greater portion of the excess of silver which, in ordinary practice, is found on the surface of the film after exposure in the camera, the developer will, after the exposure, yield only a scarcely visible image. If we then pour upon the negative a solution of nitrate of silver, the image will take what it requires from the silver, and manifest itself strongly. Now, if instead of limiting ourselves to washing the film in abundance of water, we re-cover it with a solution of the reducing salt, which, combining with the silver in excess, is carried away with it during the washings, and we afterwards expose it

in the camera, we should have to submit it anew, after submitting it to the action of the reducing salt, and no trace of the picture will be revealed, although the principle of this image exists, since it appears, as in the preceding case, in presence of a solution of nitrate of silver.

Let us carefully consider the difference of the two results. In the first case, a washing in abundance of water, the production of a thin picture; in the second case, a washing followed by immersion in a solution of the reducing salt, and entire absence of a picture.

It is, therefore, well established,

1st. That no picture manifests itself without the presence of an excess of silver upon iodide of silver.

2nd. That if water alone is insufficient to remove all this excess of silver, it is not the same with the reducing salt, which combines with it, and removes it during the washings in water, which must always follow the immersion of the negative in the developing baths.

Now that it is demonstrated that the developer removes from the iodized film all the salts of silver in excess, and that then this iodide, although sensitive to light, manifests evident alteration only after it is put, subsequent to exposure, in presence of a fresh solution of silver—we have the solution of our problem.

For, if, on the one hand, as we have stated above, the picture manifests itself only imperfectly under the action of the developing salt when the impression by light is weak, and that in such case it suffices to strengthen this image, to prolong or renew the exposure; if, on the other hand, the image formed by the silver impressed by light and precipitated by the developer, retains its photogenic properties, while they are not stopped and destroyed by the de-iodizing of the collodion by means of hyposulphite of soda, or of cyanide of potassium, it will be sufficient for the operator to impress his negative by light, and afterwards bring out the image by a reducing salt and washing the negative many times in abundance of water. The negative in this state must be kept in the dark until the moment we are ready to modify the design obtained. If we desire to lighten certain parts to give them more brilliancy or importance, as we must in those parts increase the opacity of the negative, the operator must expose it to the light, taking care to intercept the action of the light by means of screens more or less directly interposed, from those parts of the design which must remain in their primitive state.

He can, at pleasure, interrupt, resume, or displace this action of light slowly enough to be able to follow it with the eye.

When he has obtained the desired effect, it will suffice, to stop it definitely, to immerse the negative in cyanide or hyposulphite, to remove from it its photogenic properties.—*Le Moniteur de la Photographie.*

(To be continued.)

THE INFLUENCE OF PHOTOGRAPHY.*

SOME day, when mankind has grown wiser, our descendants will smile at the folly which distinguished and decorated the so-called "reformers," who make a noise in the world—and not much more—and will transfer their admiration and their honours together to the true revolutionists, the men of science. It is from the closet and cabinet that the movements originate which shake the earth. The chemist, compelling some new element to the service of man, or explaining for him the occult operations of nature; the mechanic, reinforcing his weak muscles with arms of iron and sinews of steel; the geologist, anticipating over his map storehouses of glittering gold, destined to become the origin of empires; the aeronaut, launching his silken bark upon a sea to which the "unvoyaged Atlantic" of Columbus was a mill-pond; the anatomist, questioning the mind of the Creator himself by comparison of all his works together; the antiquarian, making the dead eloquent, and eliciting from

* Daily Telegraph.

jaw-bones that died in company with mastodon and mammoth, the story of the primeval earth—these, and not the jaunty gentlemen in stars and ribbons, are the men whom history will take note of.

Photography—almost the latest born of scientific inventions—is a proof of what we mean. At first only the experiment of the savant in his study, it has become in turn an elegant amusement, a trade and a necessity, until we almost wonder how our forefathers managed to be satisfied with silhouettes and miniatures. It would take all the columns that lie before the reader even to touch upon the thousand and one ramifications of the simple discovery which lies at the base of the art now so widely practised.

Who is to say what results may follow from the vast mass of physiognomic material which hundreds of cameras are constantly storing up? Who ventures to estimate the exact consequence of the curious familiarity which we now enjoy with the persons and peculiarities of anybody in any way "distinguished?" Who knows what comfort that simple bit of card, stamped with the sure veracity of the sunlight, has brought to the absent, the exile, the captive, the sailor, the mourner? And now we are discussing the experiments of Signor Negretti, made at the audacious height of miles in the air, and with the ear of a balloon for the "dark room." If these succeed, what change may not come over the practice of war?—if, indeed, it is to outlive all the "aids" of science. How is a general to conceal his plan of attack, or mask his advance, when the photographer has him and his army under a Voigtländer lens, and can drop a "correct likeness" of the enemy into his employer's camp every quarter of an hour. Or what unknown land will keep sources of grand rivers and gorges of mysterious mountains any longer from our knowledge, if the Spekes and Grants of the future are to sail calmly over cannibals and cataracts, focussing everybody and everything at a height where the eagle would grow dizzy? These are speculations to-day, but not half so extravagant as it would have seemed thirty years ago to promise that, with a few chemicals and a square of coated paper, exquisite and absolutely truthful pictures could be produced, shaming the minuteness of the most painstaking miniature painter—still more that the artist would take his subtle palette into the skies, and, with the sun-beams for a paint-brush, limn "Mother Earth" as the stars and planets see her.

But descending to *terra firma*, photography has lately assumed a most curious function there—that, namely, of a religious reformer. If any idea could be pronounced *bizarre* beforehand, it would have been, we should think, that the invention of M. Daguerre could have any possible connection with the decline of Mahomedanism, much less conduce to it. There is a well-known song, the wit of which lies in bringing together the most unexpected people; making Æneas play whist with the "King of the Cannibal Islands," and Charlemagne—or somebody equally astonishing—dance a polka with Mrs. Fry. Hardly less grotesque must it seem to those who know the habits of the East to read that photography is just now the rage at "the Sweet Waters," and that all Constantinople is "agog" for a portrait of the Sultan. A sharp-witted Turk named Abdullah, who has imported the art into the East, has persuaded "the faithful" to petition His Majesty *en masse* for "cartes de visite" all round; and the Sultan, no ways loath, has consented, it would seem, to be made immortal "in this style." Considering that the windows of "the infidels" are full of the portraits of their charming princesses, and that everybody, thanks to the practice, knows the blood-royal by sight as well as his own sisters, it might seem unnecessary for us to criticise the desire of Stamboul. But when it is recollected what Mahomet would have to say about such a thing, and how energetically the Koran, in its heat against idolatry, denounces "the picture of any created being," it must be decidedly a sensation to an orthodox Moslem to hear that the Viceregent of God, the Padishah of all believers, has "given a sitting." We get our word "Arabesques" from the geometrical or running adornment with which old Saracenic and Mussulman art, jealous of any imitative outline, ornamented its books and houses. Now, if the Ulemas don't quickly call the convocation of Islam together and write a number of pastoral letters in the papers, the awful heresy of Abdullah will prevail, and a good Turk will boggle no more at having his picture taken than at adultery or at cheating a Christian. Mahomet foresaw a good deal, but not the photographic camera, or there would have been a special chapter in the Koran against that "device of Eblis."

Thus silently the spirit of change is stealing over the fierce faith. It made its last wild struggle for Islam "unaltered and dominant," in the Indian mutiny. The outbreak at Jeddah, in Syria, at the Lebanon, were bursts of the same angry but fading flame; and in our day the Mahomedan Crescent is on the wane. It submits, with the patience of a tamed thing, to the hand of science; it wears the pantaloons, drinks the wine, apes the vices of civilization; and will soon come to believe that Allah has had other prophets beside the famous husband of Khadijah, "whose heart the angel Gabriel himself took out with a knife of adamant, and, washing it in the golden basin of faith and truth, replaced it sinless." Pending the inevitable revolution which is thus spreading from the centre of Islam to its boundaries—a revolution possibly tedious, and certainly slow—we must not expect too much from Turkey. It is something that she has a Sultan who, if he is a little extravagant in his fêtes at the "Sweet Waters," gives his *carte de visite* away instead of purses of gold; and presents stereoscopes, like those shown in the Exhibition, to the dark-eyed houris of his zenana. Science will certainly never run the bill up on this head to the figures quoted the other night by Mr. Baillie Cochrane. "For thirty-six wives," £70,000 per month; for 1,780 "other ladies," £18,000 a month; £7,000 per month for gentlemen of a peculiar description to attend upon this feminine family; with £24,000 beside for bon-bons, sweetmeats, kubobs, and pillaws; and £80,000 for attendants—the items were, it must be confessed, alarming. But all that was in 1659, and the friends of the empire must be allowed to be hopeful in 1863, when science has slipped into the harem, and the Commander of the Faithful submits his sublime visage to the pose desired by Abdullah the photographer.

THE GLASS-HOUSE.

THE first thing which claims the attention of the photographer, is to secure to himself suitable rooms. In many instances the artist has the privilege of superintending the construction of his glass-house or operating rooms; in this case he must not only know what is required in such a construction, but he must know what arrangements are the most appropriate. The success of many an artist depends upon the fortuitous advantages of his glass-house; but these fortuitous advantages depend upon fixed laws and principles which the photographer must learn, if he is still ignorant of them.

To be brief, contrast between light and shade is agreeable to the eye whether tutored or untutored; whereas uniformity of light or of shade is very displeasing. It is not known why this is so, any more than why harmonious combinations of notes are delightful to the ear, or why non-coincident vibrations produce discord.

By means of a *happily arranged* contrast of light and shade, a stereographic roundness is communicated to pictures, which, where this contrast is deficient or quite wanting, are flat and in no way satisfactory; and where the contrast is exaggerated, where the lights are very bright and the shades very deep, where the transition from one to the other is direct, and the line of demarcation between them is almost visible, the roundness becomes a complete distortion of solidity. This distortion, arising from a vulgar contrast, is sometimes so great as to cause the sitter to disclaim his own picture. The qualifications of an artist are very distinct from those of a mere operator; the former by reason of his qualifications, can associate with gentlemen and the intelligent; the latter can aspire to no higher companionship than with the ignorant and vulgar. But the qualifications in question are attributable in a great measure to a thorough knowledge of light in reference to his art whereby *nature becomes natural*.

If an object be placed so that the light in one direction, whether brilliant or dull, falls perpendicularly upon its surface, the picture will be flat and disagreeable, because there is no contrast; if the light falls obliquely the contrast will be displeasing according to its intensity, because the shadows will be elongated and distinctly marked from the lights. A single light, therefore, can scarcely be said to produce an artistic satisfaction.

Two *equally bright* lights in opposite directions, or rather at directions at right angles to each other, are very objectionable, because either produces a bright circle of light in the eyes, which is repugnant to an artist's feelings from the fact that the picture besides is severely flat for want of contrast.

If light proceed from two directions at right angles to each other, or somewhere in the neighbourhood of this angle, of which one is more brilliant than the other, then it is possible so to arrange the sitter or model as to satisfy a cultivated taste.

The greater the brilliancy of the light, the more *unmanageable* it becomes in the production of that soft merging of light into shade which in photography is so much required. It is, therefore, quite objectionable to use the direct rays of the sun in taking portraits. But during the day these rays proceed from three directions of the compass; in the morning from the east, at noon from the south, and in the evening from the west; from the north alone in the northern hemisphere the rays never emerge. But the northern sky or space is illumined by the direct light from the sun, which by reflection and diffusion has parted with so much of its offensive brilliancy, and is rendered soft and manageable.

The direct light into the glass-house, therefore, must *enter from the north*; this is the light which performs or is to perform the principal part in the production of a photographic negative or positive. Now this single light, which enters from the northern part of the hemisphere, or a portion of it at least, may be softened down by reflection from side screens, and so directed by them upon the sitter as to make any degree of agreeable contrast. With these principles in view the glass-house must be constructed. If the operating room is situated in the highest story of a house, this house ought to be at least as high as the adjoining or contiguous buildings; and the glass window on the roof must be quite unobstructed by chimneys or trees in a direction perpendicular to its surface.

Supposing the ends of the building in which it is required to construct a photographic establishment, face east and west, the following arrangement is one which I would recommend:—Let the southern side wall be raised until it is as high as the ridge of the roof; in like manner fill up to the same height the triangular space in the end wall between the chimney and the southern wall now raised, either on the eastern or western end as it may happen to be; at a distance of fifteen feet from the end wall raise another equally high and parallel with it from the southern side to the ridge of the roof. Next construct a water-tight flat roof beginning at the side and running towards the north about ten feet. Where this terminates introduce the wooden frame (the southern portion inclining to the horizon towards the north at an angle of 45°) to contain the skylight, which may be fifteen feet wide by twelve feet deep, and inclined at an angle of 45° with the horizon and facing the north; the southern part of the frame and the window, therefore, comprehend a right angle.

Where it is practicable, it is as well to have a window in either of the end walls, furnished with sets of tight shutters, about four feet wide and proceeding (in direct contact at the commencement with the part of the skylight nearest the north) downwards to within two feet of the floor. Such side-lights can frequently be used instead of screens; and by the adjustment of the shutters light can be admitted as required, either as regards quantity or direction, that is, from the west in the morning and from the east in the evening. From the lowest part of the skylight downwards, and right across the room, the space is boarded up about four feet deep; and then the remaining part over head is a flat ceiling as far as the northern side of the building. The length of this room must be about thirty feet. The dark chamber of the ordinary work-room may be constructed on the northern side, the window of one being glazed with an orange-yellow coloured glass in order to absorb the actinic rays, and the other with common crown glass. On the

outside of the side windows small platforms are formed for the reception of the printing frames, where no other room can be had separately and especially for the direct-printing department. The skylight and the side-lights have to be furnished with curtains in order to soften or modify the right, which has access, according to the circumstances of the case or the taste of the artist.

The backgrounds are placed in the space beneath the flat roof on the southern side, and so far back as to cut off as much as possible the direct rays upon the head of the sitter. The northern end must be prepared with a greyish coloured paper, the more uniform the better, so as to keep this part as feebly lighted as possible. It is even advisable to have the part where the camera is situated entirely curtained off from the remaining space; by such an arrangement the operator requires no focussing cloth, and the curtains being of some material such as wool, and of a deadened colour, the sitter's eyes are never strained by looking in this direction.

It happens, however, very frequently that photographers cannot direct the construction of their rooms, and that the skylight is inserted directly into the slanting side of the roof. In this case, if the light comes from the north, the room will have a direction from east to west; the sitter being placed at either end according to circumstances. Here only one side light can be used; to compensate the want of a southern side light, a screen moveable on an axis is placed in its stead, which, receiving light either from above or the opposite side, can be made to reflect the same in the direction required.

Where the ridge of a roof of a building is directly north and south, and a skylight has to be constructed on the slanting roof, there seems to be no alternative but to make two skylights, one on either side, furnished with thick curtains on the inside, and on the outside with a tall partition between them, as also one on the southern side to exclude the direct rays of the sun; or to construct a suite of rooms by raising one of the side walls of the building as nearly in accordance with the plan first proposed, with those exceptions only which the nature of the building would demand.

For instance, if the building were somewhat wide, there would be only one side window; and the facilities for printing would not be so great, unless some room could be fixed up with a southern aspect.

The illumination of the background by the light from the skylight just described is uniform, because the construction of the frame admits an equal quantity at the top and at the bottom. The ordinary mode of erecting the southern part of the frame which supports the skylight, in a position perpendicular to the horizon, excludes much of the light and forms a shadow on the upper part of the background, unless a contrivance of reflection over head causes the light to be equally and uniformly distributed.—*Humphrey's Journal*.

INSTANTANEOUS PICTURES.

HUMPHREY'S JOURNAL lays down the following conditions in order to be able to take an instantaneous picture:—

The light must be very bright.

The atmosphere must be very clear, if after rain so much the better.

The lens must be well corrected and capable of working, so corrected, with a large aperture, the larger the better. The collodion, the silver bath, the developer, and intensifier must all be pure and normally good of their kind.

The camera-box must be provided with a means by which the tube can be opened and closed in the fraction of a second, an operation that may be performed with a dexterous hand holding a black cloth.

With such conditions you may succeed, but not always, by proceeding as follows:

Coat your plate with collodion and sensitise as usual, then expose to the view as instantaneously as possible.

Develop with a freshly made iron developer containing 30 grains of the protosulphate of iron to the ounce of water mixed with two drachms of acetic acid and one drachm of alcohol: or the same solution if the protosulphate may be used without the acid.

As soon as the picture appears to assume a slightly foggy film, which will soon be the case where no acid is mixed with the developer, wash thoroughly.

Fix with a solution of hyposulphite of soda, and be careful that the picture is thoroughly fixed. Afterwards wash again and again in order to get rid of every trace of the hyposulphite.

By examining the picture at this stage you can easily see whether it is a negative or not; if all the three gradations of light, middle tone, and shade are present, it is a negative and can be intensified until the shades are quite opaque; if, on the contrary, there are no middle tones, you can never convert it into a respectable negative, all that you can make of it will be a picture in which the contrast is purely black and white, of course as black as you have a mind to make it.

Now intensify, as soon as you are satisfied that you have a picture endowed with the proper conditions, as follows:—Dissolve iodine in a dilute solution of iodide of potassium and dilute until it has a light sherry-wine colour; pour a sufficient quantity of this solution over your still wet negative; move it about on the surface; pour it on and off until the film of the negative begins to assume a slight yellow tinge; then wash thoroughly. The solution by this operation parts with its iodine and becomes decolourised; and it sometimes happens that you require a second manipulation in iodizing, because the first solution was either too weak or too small in quantity.

As soon as the negative is carefully and thoroughly washed pour upon it a sufficient quantity of the following solution:

Pyrogallic acid	1½ grain
Acetic acid	1 drachm
Water	1 ounce
Alcohol	8 drops.

As soon as the plate is well covered with this solution, pour the latter off and add to it six drops of a solution of nitrate of silver, containing forty grains to the ounce of water, and shake it well. Now pour this solution upon the negative, on and off, until the shades are sufficiently dark; if the latter do not increase in opacity to your desire, take another quantity of the pyrogallic acid solution, to which six or eight drops of the silver solution have been added and repeat the operation even to the third time if it should be requisite.

As soon as the negative is sufficiently dark, the plate must be well washed, dried, and varnished.

You will easily remark that the difference between this process and that of taking an ordinary negative must consist essentially and solely in the amount of light which a given lens can concentrate upon the collodion film; for we find, that if a plate be exposed instantaneously without a lens, the actinic action is sufficient to produce a complete blackening over the whole surface when the plate is subjected to the influence of the developer. It appears surprising to those unacquainted with the laws of nature, when they behold that which we denominate an instantaneous picture. But when we consider that light, during the twentieth part of a second, has had time to rush over nearly ten thousand miles, we shall be able to conceive something of this most wonderful phenomenon.

Correspondence.

DOUBLE PRINTING.

SIR,—As I see from your journal that double printing is being brought under notice, I send you two different ways in which I have used it. I have gained so many useful

hints and information from your pages that I am willing to add my mite in return.

The first is a panoramic view of a nobleman's hall. My camera only took views eight inches square, and the only way I could take the view was in two parts of eight inches each. I had seen similar views taken and printed on two separate pieces, but the idea occurred to me to print them both on one sheet and so avoid the ugly seam in mounting them. I did this by pasting a slip of paper on each, running up a line in the building so that each half fit to the other, hiding or shielding one-half of the excited paper while the other half printed; then I passed a universal even tint over the sky—which was white—softening it off at the horizon by a pocket-handkerchief. I gave a quantity so printed at an exchange photographic society, of which I was a member, in or before 1857, about six years ago.

The other is a moonlight view on a river. The first printing was from an intense negative, so as to give sparkling high lights on the trees and bank. When printed deeply on another glass, I painted a round moon in such a place that it came partly behind the branches of a tree: the second moon I painted to be its reflection in the water; some high lights I preserved on the trees and banks by cotton wool. It is some four years ago since I did them.

My opinion of double printing is that it ought to be used only with great judgment, not an indiscriminate use made of it. I think that the general adoption of it by persons of all degrees of attainments would lead to the production of very questionable things in the way of good taste. How far I have succeeded in the moonlight effect, I have laid myself open to criticism. In the panoramic view I looked upon it as a necessity.

I work by the collodio-albumen dry process, and have—may I say invented?—a stand for developing, or other purposes, which, for simplicity and convenience, I think cannot be surpassed. My plates are 10×8; into a 12×9 dish I place a preserve or marmalade jar, six or seven inches in diameter; in the jar I place a round-bottomed or common plain stop bason, and it gives me a large ball and socket hinge, that I can elevate or depress on any side, and to any angle, allowing the plate to develop more or less on any side, or it may be perfectly level.—Yours, truly,
THOMAS KIRBY.

Trentham.

[The panoramic picture shows admirably the value of the principle in question. The moonlight is not so successful. We doubt very much the legitimacy of the attempt. It is certainly one which will rarely succeed.—Ed.]

ON THE MOTION OF CAMPHOR TOWARDS THE LIGHT.

SIR,—In a letter published in your journal of the 17th April last, I endeavoured to show that Dr. Draper's claim to the discovery of the true theory of the motion of camphor towards the light could not be supported, and that the result of his experiments, as republished in 1844, was merely to multiply the phenomena, and to leave the theory as it was.

Dr. Draper has since published a letter in the *Philosophical Magazine*, in which he affirms that I admit that he published the true explanation of these motions in 1840; and he also accuses me of having founded my remarks on experiments of his made in 1837. I have replied to these charges in a letter to the *Philosophical Magazine*, the substance of which I hope you will allow me to repeat here; but I must be permitted to remark that the later, as well as the earlier experiments, as given by Dr. Draper, equally fail to explain the true theory, and that with the fine opportunity of correcting them, afforded by the republication of the whole in 1844, it is incredible that they should have been presented without note or comment, and illustrated with new engravings, had the author been at that time in possession of the true theory.

In my letter to the *Philosophical Magazine*, I state that I have never had the slightest intention of misrepresenting

Dr. Draper, or of detracting from the merit due to his industry and skill. But I deny that the paper which he published in the *Philosophical Magazine* in 1840, or his volume of 1844, contains the true theory of the motion of camphor towards the light, or that I ever admitted that it did so. The former contains a question which, had it been followed out, and properly tested by experiment, might have led to the true theory; but that it was not thus tested is proved by the fact that in the volume of 1844 it was again published as a question, and nothing more.

I now leave my claims, and those of Dr. Draper to be settled by reference to my papers and his volume. But I think it will be admitted that the latter, full as it is of details of ingenious experiments, leaves one as much in doubt at the end as at the commencement, and cannot possibly be considered as the earlier and later steps of a successful inquiry. Indeed, it is so difficult to trace any consecutive steps, that the volume was viewed by me as a whole, and as containing the latest revised opinions of the author.—I remain, &c.,

C. TOMLINSON.

King's College, London, June 9th, 1863.

Proceedings of Societies.

THE AMERICAN PHOTOGRAPHICAL SOCIETY. FORTY-SEVENTH MEETING.

The Society held its regular meeting for April, on Monday, 13th inst., at the University, President DRAPER in the Chair.

The Minutes of the last meeting were read by the Secretary, F. W. GEISSENHAINER, Jr.

Mr. RUTHERFORD said that the statement made by Prof. Joy at the last meeting, that he had succeeded in photographing the entire visible spectrum, was erroneous. On the contrary, he had never been able to obtain any photographic effect, beyond the middle of the green, although he had submitted to a strong light a most sensitive surface.

Printing and Toning.—The subject for the evening having been taken up,

Mr. BURGESS inquired what was the best manner of applying the silver solution to the paper for albumen prints. His practice had been to use the ammonia-nitrate solution:—Take eight ounces of water containing silver and convert one ounce into a solution in the ordinary manner, and then mix it with the other seven ounces, and filter. Float the paper five minutes, and dry and print it; sometimes he submitted it to the fumes of ammonia.

Col. PIKE said that recently he had used for his floating bath forty grains of silver to the ounce of water, into which he dropped a few drops of concentrated ammonia. He had been experimenting with nitrate of ammonia, and had succeeded in the following manner:—He dissolved three drachms of nitrate of ammonia in a few drops of water; then in half an ounce of water he placed ten grains of nitrate of silver. He then added concentrated ammonia enough to make it turbid, and threw down all the silver he could without clearing it. This he added to the nitrate solution, and it cleared it at once, so that it was unnecessary to filter it. He used this with paper salted with only one grain to the ounce, and it made fine prints which toned up admirably. The addition of ammonia to the nitrate of silver bath seems to accelerate the printing; he inquired what was the chemical reason for this?

Professor SEELY said that he had not yet found any satisfactory exposition of the action of ammonia. He did not see that nitrate of ammonia would be of any service, unless it is a coagulator of albumen. It would seem theoretically that it would be better to wash away the nitrate of ammonia and redissolve with ammonia alone. There are several objections to a weak solution of silver with albumen paper. In the first place, the albumen surface is more liable to be disturbed. Adding some substance to coagulate the albumen might overcome that difficulty. With the albumen perfectly coagulated, a solution of three to five grains could be successfully used, in all probability, as an experiment. Still it would not be practicable for real business. The nitrate of silver solution would rapidly deteriorate in strength. An iodide or a bromide which would be little soluble in water would permit a weaker solution of

silver than the ordinary nitrate bath. Another question connected with the subject for the evening was the new fixing salt, the sulpho-cyanide of ammonium. He was not inclined to recommend it. One objection to it is that it is poisonous. The sulpho-cyanide of potassium, which is similar to it in its action, is less poisonous probably; and it is very easily and cheaply made. Take two parts of the yellow prussiate of potash and melt with one part of sulphur, and it produces the sulpho-cyanide of potassium contaminated with a little metallic iron which may be filtered off; or, boil flower of sulphur in a solution of cyanide of potassium until it begins to turn yellow. Still the advantages from it are not sufficient to warrant much consideration of these experiments.

The PRESIDENT remarked that it had been asserted that the sulpho-cyanides were not poisonous, and probably because one of them existed in saliva; but it was not a constant ingredient, and when there, it was in very minute quantities; so that he did not regard this a justification of the assertion.

Professor SEELY suggested another objection to both these salts, that any excess of alkali would take the albumen right off the paper. It is stated also, in the PHOTOGRAPHIC NEWS, that it yellows albumen paper.

Mr. BURGESS inquired what was the best quantity of silver to be used in silvering paper. He had used from 90 to 120 grains to the ounce.

Col. PIKE gave his toning process as follows:—Put in stock-bottle No. 1, 60 ounces of water and 100 grains of acetate of soda, or 75 grains each of acetate and phosphate of soda. In stock-bottle No. 2, put 1 ounce of water and 15 grains of chloride of gold. In stock-bottle No. 3, put 15 grains nitrate of uranium to 1 ounce of water. This will suffice for 150 pictures. Take from stock-bottle No. 1, 8 ounces; from No. 2, 2 drachms, to be neutralised with carbonate of soda; from No. 3, 2 drachms, also to be neutralised; mix and filter, and it is ready for use. For a fixing bath I use $\frac{1}{2}$ -pound hyposulphite of soda in 20 ounces of water. This bath must never be used twice, or it will yellow the whites of the pictures.

Mr. MASON had used a very similar process with success. For the gold solution he used 30 grains of chloride of gold in 6 or 8 ounces of water.

Mr. CRUM had also used a similar process. For a silver solution for floating albumen paper, he had used from 120 down to 40 grains with nearly equal results. First introducing in it ammonia to form a precipitate, and then clear up, he added a few drops of nitric acid, and about a drachm of alcohol to eight ounces of the solution. He thought the alcohol tended to preserve the albumen surface.

Mr. MASON exhibited some pictures taken by Mr. Masterton (which were commended by several members), and inquired the process.

Mr. MASTERTON said that he used a nitrate bath of 60 or 70 grains, fumed the paper about twenty minutes, and floated it about three-quarters of a minute. He did not use ammonia-nitrate, but generally put a little citric acid into the solution.

Col. PIKE suggested washing prints with boiling hot water.

On the motion of Mr. BURGESS, the subject of Fixing and Toning was made the subject for consideration at the next meeting.

Heliochromy.—Mr. TILLMAN read a paper on Heliochromy. (See p. 270.)

Stellar Spectrum.—In reply to an inquiry by Mr. Tillman, Mr. RUTHERFORD said that he was still engaged in observing the location of the lines in the stellar spectrum; and had so improved his apparatus as to see the lines with greater facility and locate them with greater accuracy than before; having added a prism so that he could see in the same field the stellar spectrum, the scale of measurement, and also the chemical lines reflected from a spirit lamp; by that means guarding against the slight movement which took place even with the finest possible slit in the spectroscope. He remarked that he had now ascertained that Arcturus presents the lines of the solar spectrum in the same places, proving a similarity between its constitution and our Sun. If made of the same materials, and if the nebular hypothesis be true, were they made of material in the same neighbourhood? If so, is Arcturus straying away from its former, our Sun, or does it still belong to the same neighbourhood in the Universe, in space? We know that other stars are not of the same materials, but there is a striking difference between them. Here Chemistry reveals a connection which Astronomy has failed to show.

Mr. TILLMAN, after alluding to the fact that the dissimilarity

between the stellar spectra seemed to conflict with the nebular hypothesis, remarked that the most splendid astronomical analogy of our time, the most sublime discovery since the days of Kepler, the law of Kirwood, an American, that the square of the number of revolutions of each planet upon its axis per annum is as the cube of the diameter of its attracting sphere in the nebular hypothesis, had been alluded to by the late Prof. Nichol as confirmatory of that hypothesis. He could only hope that some explanation might be found for the facts discovered by Mr. Rutherford, which would make them consistent with that view, because it seemed to him to give, above any other theory, the most exalted idea of creation and the Creator.

FORTY-EIGHTH MEETING.

THE Society held its regular meeting for May, on Monday, 11th inst., at the University; L. M. RUTHERFORD, Esq., Vice-President in the chair.

Toning and Fixing.—This being the subject for the evening,

Mr. BURGESS started the discussion, by inquiring what proportion of hyposulphite was generally used in solution? He used 1 ounce of hyposulphite to 8 ounces of water, and found that proportion to work successfully.

The CHAIRMAN asked if the inquiry was suggested by any misgivings on the subject of that being the proper proportion?

Mr. BURGESS said not; that he merely wished to know what the practice of others was.

Mr. CRUM mentioned that the proportion he sometimes used was 2 ounces of hyposulphite to 10 ounces of water. So far as his observation was concerned, he questioned whether there was any staple formula. He thought, as a general thing they used too little hyposulphite in fixing prints.

The CHAIRMAN wished for some light on the question; what was the chemical action of toning—whether the metal gold really took the place of the metal silver in the print, and if that was the theory what produced the result.

Professor SEELY said such was the theory, but still the proof could not be of the most positive character. The print was changed by the gold; it was pretty certain the gold was deposited there, and if deposited there, we could not but suppose it took the place of the silver. In the Daguerreotype process, we knew that the gold from the gilding solution was deposited in the metallic state upon the silver. The silver of the collodion negative we knew to be in the metallic state, and when a solution of chloride of gold was poured over it, the gold was removed and the image took the same colours as were seen in toning paper prints.

The CHAIRMAN had been struck by two facts that led him to doubt there was any metallic substance, properly called, in the construction of the print, when finished. In the first place, the fact that the print, or material of which the image was formed, disappeared, leaving a white surface, which seemed to be inconsistent with the idea of there being present one of the royal metals, particularly gold, which did not oxidise and still less evaporate. The other fact was that, in experiments with paper treated in the ordinary way, and made as dark as possible, he had found it no better conductor of electricity than a piece of plain paper. We knew that gold and silver, in the minutest shape to which the gold-beater could reduce them, were good conductors; but on photograph paper the spark jumped it as it would a vacant space. These two facts threw suspicion upon the existence of gold or silver in the print, in a metallic form. About two and a half years ago he had two hundred prints made of the surface of the moon, about four inches in diameter—beautiful prints, executed by one of our best artists. They lasted perfectly well for two years; and at the end of that time began suddenly to deteriorate, until now they were almost white paper.

Mr. BURGESS thought that albumen paper was more likely to retain the image than plain paper.

Mr. CRUM was of opinion that the metal must be in the print, for when we chlorodise metal we knew it was there in existence; and the experience of every operator was that, as the gold was taken up from the bath by the prints, the toning depreciated; so that while the first prints immersed in the toning bath printed very rapidly, gradually, as the gold became absorbed, they toned slower and slower, until the prints ceased to tone at all, and no gold was left in the bath. The question then arose, what became of this gold? It was certainly an indestructible element; it could not evaporate, and it must be in the print. By paying special attention to the toning—using sufficient gold and good chemicals—he found that his

pictures did not fade, but rather improved by age. He had abandoned the use of plain paper altogether, except for photographs coloured in water, finding that albumen paper was much superior.

The CHAIRMAN inquired if any gentleman had tried the formula of their late secretary, Mr. Thompson, by using brass as a substitute for gold. He had received from Mr. Thompson some beautiful prints on albumen paper, which he stated were brass toned.

Mr. CRUM did not think they would last any length of time.

Mr. TILLMAN thought the question an important one to consider; of course there was no similarity between brass and gold, except in the colour, and the question was, whether that peculiarity in the brass which presented the yellow ray was not the very quality or virtue which was necessary when used in the art. He was not prepared to discuss this, but it opened a wide field of inquiry.

Mr. BURGESS said that he understood that another substance, bichloride of mercury, had been used, and with great success so far as getting colour, but the pictures were found to fade soon. Mr. Anson had told him he used it for a time, but returned to gold again.

Mr. LOOMIS stated that he had, in a number of experiments made, produced very vivid tones with bichloride of mercury; there was no difficulty in giving any required tone of red, to the deepest purple; but he had never succeeded in producing any prints in this manner that would stand. He found that he could instantly restore prints which had faded almost white, to a purple tone, with bichloride of mercury. He also found that almost any print he had ever seen could be removed with the fumes of nitric acid. That fact seemed almost conclusive that there was no metallic gold in the print.

Mr. TILLMAN suggested that if any one felt disposed to try Mr. Thompson's formula of using brass, instead of gold, he had better use the oreide, which was the purest kind of brass.

Prof. SEELY said that the bichloride of mercury process was by no means new. He had published an account of it eight years ago, and his experience was the same as others, that the pictures were not permanent. As to toning with brass, it was evident that if the gold were used in an alkaline condition, no zinc or copper of the brass would be held in the solution.

Electro-Daguerreotypes.—Mr. PLUNKETT presented for the inspection of the Society some electrotypes, made from a daguerreotype, which were very perfect. He stated that the copper was deposited on the daguerreotype plate, and one of those produced was the ninth one taken. There was no difficulty in separating them. He passed the plates over the fumes of boiling beeswax.—*American Journal.*

BRINGING HOME THE MAY.—We learn from various sources that Mr. Robinson's charming picture is the cynosure of all eyes, and the chief attraction at the French Exhibition. M. Lanlerie, secretary of the French Society, in a private letter, speaks in the highest terms of the admiration it receives from French photographers. *La Lumiere* styles it the pearl of the Exhibition, and thus describes it:—"Bringing Home the May" is a large composition 40 by 16, illustrating an English custom. Young girls and children are engaged in gathering the wild May flowers, or are carrying large burdens which they have just gathered. Their features are lighted up with mirth and gladness, as they enjoy themselves amid the beautiful foliage. Every part of the picture is perfectly made out and distinct down to the smallest blade of grass, and whilst the picture has been produced from at least three negatives, there is perfect harmony and keeping, the whole being rendered with exquisite perfection. This fine production is by Mr. H. P. Robinson, of Leamington; and although it may be regarded as a *tour de force*, it is one more proof, amongst thousands, of the exhaustless resources of photography, and illustrates the perfect success which crowns the skill and patience of the artist when thus applied." We have before stated that this exquisite picture is from seven different negatives. That there is no evidence of patchwork, is illustrated by M. Gaudin's conjecture. Mr. Robinson is engaged upon another large composition, and we think the fact that an artist engaged personally in a very extensive portrait business, which absorbs almost all his time and energies, still produces yearly, at least one such composition as that we have noticed, suggests that if the work in question be a *tour de force*, it is one which need not be an isolated example if the artist had more time at his disposal.

To Correspondents.

W. H. T.—Good glue, clean and freshly made, may be used for mounting photographs with advantage. The Scotch glue is generally used by professional mounters.

M. P. has accidentally mixed his silver solution and his developing solution together and wants to know what he shall do with them. The iron will reduce the silver into a metallic state. The completeness of the operation may be facilitated by boiling in a glass flask. When all the silver is reduced, which may be ascertained by adding a little of a solution of common salt to the mixed solutions, and observing whether any turbidity is caused, indicating the presence of unreduced silver, the grey precipitate at the bottom, which is metallic silver, may be well washed, and reconverted into nitrate of silver as we have often described. 2. We do not find the rosin cement, to which you refer in your letter; if it were made according to the formula given on page 195, *PHOTOGRAPHIC NEWS*, Vol. VI, it would be right. 3. The shellac varnish is right; but it must not be used over the rosin cement as it would probably partially dissolve it. You may use either alone for vessels to contain photographic solutions. 4. Yes; it is right. 5. Also, right. 6. Your bath will do if you have made it so that it will not leak. 7. Wash out the bath with dilute cyanide solution to remove the traces of reduced silver, and rinse well. 8. A bath of pure gutta-percha may be used safely, especially if the bath be not kept in it constantly.

FORMIC ACID.—A Correspondent, signing "Charity," writing on this subject, says:—"Since Mr. Henry Claudet introduced this active acid to developing, innumerable "mares' nests" have been, and will, doubtless, be discovered; still, it is just possible that some of them may ultimately turn out useful to the art. With this hope I procured no less than six different kinds of this acid manufactured by as many different means, and all from different sources. I find on trial that they all approximate in result to that in the formula published by Mr. Claudet, so closely that it would only amount to plagiarism of his communication to trouble your readers with details. K. Staunton has restated the process in a recent number with slight variation, and the process I think merits all he said in favour of it. However, each respective operator will and must determine for himself the quantity of acid necessary for the production of the best pictures by actual experiment; and as each operator considers himself superior to every other in some particular point, each may assist all by contributing some slight variation. I find the period of exposure reduced certainly one-half.

THE CAUSE.—The spot in the print you forward is caused by some imperfection in the albumen surface, or rather by the absence of any albumen. Its absence may be the result of imperfect preparation, or of something having removed it from that place before the paper was sensitized.

AN AMATEUR.—Of the two lenses by the first maker you name, the 1 B and 2 B, the latter is of longer focus and larger diameter than the former. It gives better definition and greater rapidity, and is, therefore, better. Where the room is long and the cost not of vital importance, it is decidedly preferable. 2. We do not know of any half-plate portrait lens for £22s.; such a lens cannot be worth much. The 1/16 lens of the English makers is generally a very first-rate instrument, and covers a whole plate well. 3. We have not had opportunity of comparing the two lenses you name, and cannot therefore give an opinion.

S. P. C.R.—Before adding fresh gold to an old lime toning bath, neutralize with carbonate of lime, using hot water.

H. G., Brompton.—The chief fault in the lighting of your figures is too much top light. With a lofty room you can afford to extend the opaque part over head still further. You also under-expose a little.

W. WILSON.—Whilst there is still room for improvement in your work, it is decidedly up to the average. You need not fear disgracing the art if you continue to do your best. The photography generally is good; perhaps there is a slight tendency to under-exposure. Study the cards of the best artists, and endeavour to acquire a little more ease in posing. In No. 1, the background is faulty, in the profile fireplace, &c., being of a much lighter colour than the background which represents another wall of the same room. With a trifle more exposure No. 2 would have been good. No. 3, a stiff position, but the rest pretty good. No. 4, good, with the exception of the perspective being false. 5. When you vignette the full length figure, the feet should be either entirely cut off, or quite retained; 6 would have been good with a little more exposure; 7 good; 8 also good; 10, photography good, accessories bad; 12, the same as last; the point of sight in the painted portion of the background, and in the photograph are not the same, and the perspective glaringly incorrect. We have spoken plainly of the faults in your work, but would speak encouragingly on the whole. With patience and care you will make a first-rate photographer.

AN AMATEUR (No. 2).—It will not be safe to use a gutta-percha bath which has been employed for hypo, for a nitrate of silver solution, even after any treatment. If you choose to risk it, let dilute sulphuric acid remain in the bath for a few hours, and then wash well with plenty of water and a mechanical friction.

SEA-SIDE.—When the plate has been covered with glycerine, and drained a short time, it may be placed vertically in the plate-box without injury. Wash again before fixing.

A. HARMER.—We see no reason at present to believe that the demand for card-portraits will abate. 2. Probably, a developer of one-fourth the strength will answer better in your hands.

A TWO YEARS' SUBSCRIBER.—Send us a specimen of the defect, and we shall be able to help you.

H. G.—See report, in our "Scientific Gossip."

AN ENGRAVER.—The method of producing the "ghost," at the Polytechnic, as we believe, the invention of Mr. Durck, and is patented, we understand. The specification is not yet published. We believe it is the result of reflection, not of optical projection. The details may be easily conceived, but we cannot enter into them here.

E. S.—The brownness you describe is simply fog. Use more citric acid in the pyro solution, or use the iron intensifier we recently described. When the fog is irregular, it is probably due to imperfect washing between the various operations. The use of a solution of iodine before intensifying will generally prevent the deposit. 2. The prints becoming of a pink colour in the back is generally due to toning in white light, causing a reduction of the gold throughout the paper, instead of on the image only.

A. Z.—We should attribute the spots in question to the albumenized paper. We only once met with a similar result, which disappeared at once on changing the paper.

SHEFFIELD.—Where rapidity is not an object, we should prefer a single lens

to a portrait combination for landscapes. But, for instantaneous work, a portrait combination is decidedly the quickest, and the definition, in our estimation, more satisfactory than can be obtained with an ordinary single lens with an aperture sufficiently large for instantaneous work. We recently made a trial of a single lens (aplanatic), and a portrait lens of the same equivalent focus, each six inches; the stop in each three-eighths of an inch (to have been equivalent stops that in the quarter-plate being between the lenses should have been one quarter of an inch). In both the perfect definition covered more than a stereoscopic picture. The single lens required an exposure of twenty seconds to produce a good negative; whilst the portrait lens required ten seconds for the same result. The light was not bright. 2. Albumen, in the collodio-albumen process, has several purposes; but it decidedly gives vigour there, and in almost every photographic process in which it is used. 3. A single lens to cover 18 by 18 should be of about 30 inches focus. 4. We have not used the collodion in question. If it fail to give intensity, either intensify or try another sample. We do not like to see over-much intensity in the sky.

C. L. O'BRIEN.—The prints enclosed in your note are, moderately good; but it is quite impossible to form an opinion of your qualifications for a professional engagement upon such evidence. It is comparatively easy for anyone to produce two or three moderately-good prints, if everything be prepared for them, and in good working order. A good printer must not only be familiar with all the manipulations in printing, such as sensitizing, exposing, toning, fixing, washing, &c.; but he must be able to prepare all his solutions, to know when they are in good or bad condition, and the causes and remedy for the latter. Also, how to deal with various difficulties, and meet the requirements of various batches of paper, and various qualities of negatives. You will readily see that we can form no opinion on these points from examining a few prints.

PERPLEXITY.—The stain has every appearance of having arisen from irregular development. The developing solution, instead of covering the plate evenly at one sweep, has run back from the edge of the plate in greasy, irregular, branch-like lines and patches. If this be the cause, as we suspect, add a little more alcohol to the developer, and manipulate more carefully. If, as you state, the markings show on the plate on removing it from the nitrate bath, they probably arise from using a collodion giving an impervious horny film. In such case add a drop of distilled water to each ounce of collodion.

SOL.—The solution of chloride of gold which you have may be used according to Ommegeanck's formula, taking care to preserve the proper proportions. 2. Chloride of silver cannot be converted into nitrate by any direct process; it must be reduced to metallic silver first.

R. H.—You may procure good lenses at many photographic establishments, but we should recommend the best London makers. The size and price must depend on the purposes for which they are required. The meaning of coincidence between the visual and chemical foci is in result, that when you obtain a sharp image on the ground glass, you will also obtain a sharp image on the sensitive plate when placed in the same plane; and unless the corrections in achromatizing the lens are such as unite the visual or illuminating rays, and the rays producing chemical action, this coincidence does not exist. It will be desirable either to get the assistance of an experienced friend, or to consult our advertising pages, and call upon the most respectable opticians, and state your wants. Chloride of gold will keep in solution. It is as well kept in the dark. Send us specimens of your difficulties or defects in printing, and we can advise you. Toning and fixing generally reduce the print somewhat, and it is necessary to over-print sufficiently to allow for this. The firms to whose advertisements you refer do not print from the cards sent, but from negative copies of them. There are instruments for measuring the intensity of light, which you may obtain of some philosophical instrument makers, but experience is the best guide. To copy a drawing the same size your camera must be drawn out to twice the equivalent focus of the lens, and be placed at the same distance from the drawing which the lens is from the ground glass. An achromatic triple lens is the best for copying. The solar camera is intended for producing enlarged prints from small negatives. It has been repeatedly described in our columns, and would require too much space for description anew in this column. You will learn particulars of any dealer. We can draw invidious distinctions as to the best producers of any photographic requisite in this column.

A NOVICE.—The apparatus in question is not suited for portraiture. We have not tried it ourselves, but should have more faith in the lenses of the best London makers. The enlarged specimens appeared to us to have considerable distortion. Mr. Scaife's Pistolgraph is a clever little camera and lens, giving very rapid results. The lenses are made by Dallmeyer.

SEVERAL CORRESPONDENTS in our next.

ERRATUM.—Mr. Ross desires us to state that his small lens for medallion portraits possesses an aperture of six-and-a-half-tenths of an inch, not eight-tenths, as stated in the report of the London Photographic Society, in our last. With this aperture it works in a fourth of the time of his card lens.

NOTE ON THE RESULTS OF MR. GLAISHER'S PHOTOMETRIC OBSERVATIONS.

BY JOHN SPILLER, F.C.S.

AFTER reading the interesting account of Mr. Glaisher's last balloon ascent, as given by him in the *Times* of the 22nd April last, I was induced to make some experiments with the view of imitating, if possible, the extraordinary conditions under which that gentleman observed, at an altitude of three miles, and in the clear atmosphere above the clouds, that surfaces of sensitized photographic paper were not so much darkened in the course of half-an-hour's exposure to direct sunshine as were similar sheets by one minute's solar action within the grounds of the Royal Observatory, Greenwich. Several causes have been assigned by way of accounting for these remarkable results, and some useful suggestions followed the announcement of the full particulars by Mr. Glaisher at the meeting of the London Photographic Society, on the 5th May. It was on this occasion stated that the thermometer indicated 21° Fahr., and that the dew point was below zero at the time of exposure. These conditions, at the altitude mentioned, are indicative of an exceedingly dry and rare atmosphere, in which rapid evaporation must occur, and the cold would be sufficiently intense to freeze very quickly any traces of water still lingering in the pores of the paper. Absence of hygroscopic moisture appears then the probable explanation of the facts observed. The verification of this opinion is, I believe, contained in the experimental results which have now to be described.

Sheets of albumenized and plain salted paper were sensitized respectively on nitrate of silver in the usual manner, and, when air-dried, were cut into slips for comparison.

1. Exposed to bright diffused daylight in a glass globe filled with air at the ordinary pressure.

2. The same arrangement; the air in the globe being exhausted by the aid of an ordinarily good air-pump, until the vacuum gauge stood within half an inch of the height of the barometric column.

3. Similar experiment to No. 2 in all respects, excepting that a piece of moistened filter paper was placed near, but not in contact with, the sensitized paper inside the glass globe.

4. Also similar to No. 2, but with a supply of chloride of calcium to absorb water from the rarefied air.

5. Without pumping out the air the paper was kept for two hours in the dark under a glass receiver, within which was a shallow dish containing sulphuric acid to absorb the moisture. At the end of that time, exposed to light beside the ordinary paper under glass for comparison.

6. The papers were kept some time in an atmosphere dried by quicklime; then exposed to light as before.

7. Slips of the paper were dried thoroughly by the application of heat, and then exposed to light under pressure between two plates of glass; similar papers in ordinary hygroscopic condition serving for comparison.

The results were as follows:—

No. 2 darkened more slowly than No. 1, and exhibited, in the case of albumenized paper, a pale lilac tint, instead of a rich chocolate or purple brown.

No. 3, in the moist vacuum, was affected by light in the same manner, and as quickly, as No. 1.

No. 4. The action of light was very much retarded, more so than in No. 2.

Nos. 5, 6, and 7, were but slowly affected, the colour of the papers being generally similar to No. 4.

The plain chloride of silver paper, and other sheets prepared with Swedish filtering paper, exhibited, in different degrees, the same general result as the albumenized surfaces.

The effect of exposure to intense cold, or artificial freezing mixtures, remains yet to be investigated, and it cannot be said that the effects observed in the course of my experiments were so decisively marked, although doubtless of the same character, as those described by Mr. Glaisher. The influence of moisture in increasing the sensitiveness of these photographic surfaces has been many times pointed out by others as well as myself, and was particularly alluded to in my "Description of a Desiccating Box for Preserving Sensitized Paper," read on the 5th March, 1861, at a meeting of the London Photographic Society. In using this apparatus I found that the sheets of sensitized paper could not be employed for printing in the unusually dry state in which they were taken from the box, but that a short interval, for re-absorption of hygroscopic moisture, must be permitted before laying them in contact with the negative.

The addition of nitrate of zinc as a deliquescent agent was tried under the impression that this substance would have furnished a more uniformly sensitive paper under all circumstances; but the result of such admixture has not proved this to be the case. The use of a bath of fluoride of silver, instead of the nitrate, for sensitizing the paper would doubtless have the effect of retarding the evaporation of water from the prepared surface, and might thus afford a means of producing papers of more definite character. I am now engaged in investigating this point, and will, if successful, communicate the results.

In the course of these experiments I have had many opportunities of noting the remarkable degree of expansion which coincides with the absorption of moisture. The dimensions of the paper frequently varied as much as one-fiftieth in the transition from moist to dry, a point which does not appear to have been sufficiently considered in attempting photometrical determinations upon paper tablets.

PHOTOGRAPHIC CHEMICALS:

THEIR MANUFACTURE, ADULTERATION, AND ANALYSIS.

URANIUM is of value in optical researches, not only on account of the sensitiveness of some of its salts to light, but

because many of its compounds possess the curious property of fluorescence, or rendering visible the chemical rays of light, by converting them into rays of a less refrangibility. Its properties in this respect have been well investigated by Professor G. G. Stokes. A beautiful transparent yellow glass, with a green tinge, is frequently met with in commerce, being largely used for ornamental purposes. If this glass be examined by candle-light, it will be seen to be perfectly transparent, and to have no green tinge, but if looked at in daylight, especially if the sun shines on it, it will become almost opaque, reflecting back a strong greenish-blue light. On concentrating a beam of sunlight on to a thick piece of this glass by means of a lens of one or two inches focus, the cone of light will be traced out through the glass by a strong luminosity, appearing as if the particles of the glass were in some degree opaque to the light. This effect is caused by the invisible chemical rays present in the incident light being lowered in refrangibility, and thereby converted into luminous rays by the action of the uranium compound in the glass. This effect may perhaps be better understood by some of our readers, if we consider the uranium glass to have phosphorescent properties, and to be excited into luminosity by the chemical rays of light.

If a slab of uranium glass be employed as a screen for receiving an image of the solar spectrum, especially if the latter be pure enough to show the fixed lines, the appearance is very striking. Where the visible spectrum falls no particular effect is produced, but as the eye travels along the band of colours up into the blue and indigo end, the lines in these parts, difficultly visible under ordinary circumstances, shine out with unaccustomed brilliancy. The line H, barely detected by the unaided eye, is remarkably prominent, and beyond, far into the regions of darkness, are seen groups of lines, some as fine as spider threads, some like great black bands stretched across, cutting almost through the slab of glass, which glows through its whole body with an indescribable phosphorescent light, except where the jet-black lines intersect it. If the prismatic apparatus be of quartz, and a fine summer's day be selected for the experiment, the length of the solar spectrum will be apparently increased four or five fold. Starting from H, near the limit of the visible spectrum, but almost the commencement of the invisible part, we see the broad band *k*, the curious group of four nearly equidistant lines, *m*, the somewhat allied band *n*, and then a host of other lines to which physicists have given letters, until the alphabet itself proves too humble for its requirements, and other lines and groups are detected faintly following *x*, *y*, and *z*. Professor Stokes, who has thoroughly investigated the action of uranium compounds upon the higher rays of the spectrum, considers that for some purposes a slab of uranium glass is not the most convenient for purposes of observation. Glass must be viewed in one particular position, in order to see the lines with the best effect, and in many cases it would be more convenient to have a screen prepared by means of a highly fluorescent powder applied like a water-colour on paper, which could be viewed in all directions indifferently. The professor states that he has long regarded it as a desideratum to obtain by precipitation an insoluble or sparingly soluble salt of sesquioxide of uranium, which should be as fluorescent as the best salts of that base, and which might be treated as a water-colour. He has recently succeeded in preparing such a salt, though not by direct precipitation. The ordinary phosphate obtained by precipitation is only slightly fluorescent. If, however, this salt, with as much water as remains when it is washed by decantation, be put into a saucer, a little free phosphoric or sulphuric acid added, and then crystals of phosphate of soda, phosphate of ammonia or borax be added in excess, the original salt is gradually changed into one which is powerfully fluorescent. The change seems to take place most rapidly with borax, but as an excess of this salt is liable to decompose the fluorescent salt first formed, it is better to

employ a phosphate. The quantity of acid should be sufficient to leave a decided acid reaction when the liquid is fully saturated by the alkaline phosphate employed. The change may be watched by observing, from time to time, the fluorescence of the salt by daylight, with the aid of absorbing media. It is complete in a few days at furthest, when the salt is ready to be collected. This requires precaution, as the salt is quickly decomposed by dilute acids (and, accordingly, by its own mother-liquor, if diluted), and even, though more slowly, by pure water, with the formation apparently of the original phosphate. It is also decomposed,—at least, in time—by alkaline carbonates, with the formation of a beautiful yellow non-fluorescent salt, resembling the precipitate given by alkaline carbonates in salts of sesquioxide of uranium. The salt may be collected by adding at once, instead of water, a saturated solution of borax, in quantity at least sufficient to destroy the acid reaction. The salt is then poured off in suspension from any undissolved crystals of the alkaline phosphate employed and collected on a filter. A pressed cake of this salt, or a porous tile, upon which the salt is spread, having been moistened with a solution of borax, forms an admirable screen. It shows, of course, the visible as well as the invisible rays—the former by ordinary scattering, the latter by fluorescence.

Hitherto the only uranium salt used in photography has been the nitrate. This seems to be rather an unappropriate salt; for since the action of light upon it is to reduce a higher to a lower state of oxidation, it is clearly inadvisable to employ as the sensitive surface a salt containing so much oxygen as the nitrate. Analogy with other photographically sensitive compounds would lead us to propose that some organic compound of uranium should be used, as, for instance, the acetate, which is likely to be far more acted upon by light than the nitrate. Acetate of uranic oxide is prepared in the following way:—Nitrate of uranium is placed in a porcelain dish and gently heated with a spirit lamp. It fuses at first in its water of crystallisation, and at a higher temperature decomposes, oxygen going off. If the source of heat is removed when it begins to evolve oxygen a yellowish-red mass is obtained which still contains nitric acid. This is heated with glacial acetic acid, when it entirely dissolves. The solution, upon being evaporated to the crystallising point, deposits acetate of uranium, the surplus nitrate of uranium remaining in the mother liquor.

When the acetate separates from a very acid solution by a slight reduction of temperature it forms yellow oblique rhombic prisms, which dissolve in water with slight decomposition and crystallize out on evaporating the solution. They contain two atoms of water of crystallization. When a saturated solution of this salt, at the ordinary temperature, is cooled to a lower degree, square based octohedra separate, which are the same acetate of uranic oxide, but with only one atom of water. If carbonate of ammonia be added to a hot solution of uranic acetate till a precipitate begins to separate, and acetic acid be then added, a solution of a double acetate of uranium and ammonium is formed. Upon allowing this to crystallize it separates in thin yellow silky needles, readily soluble in water and slightly acid to test paper. They are not decomposed by water even when boiling. In a similar manner double acetates can be prepared containing uranium and potash, soda, ammonia, &c. As these are in every respect stable salts it is more than probable that really valuable photographic compounds may be obtained from them.

ON DEVELOPING THE PHOTOGRAPHIC NEGATIVE.*

BY M. AUG. TESTELIN.

WHEN a negative developed with pyrogallie acid is nearly completed, there forms a yellow deposit on the surface, or rather a sort of fatty film so adherent that a stream of water will not detach it. This deposit arises from the decomposi-

* Continued from p. 167.

tion of the pyrogallic acid which absorbs the oxygen of the oxide of the metallic salt: the nitrate of silver is then partially transformed into insoluble ellagic acid, and is consequently deposited proportionally to the development of the image, that is, during the reduction of the nitrate of silver.

Ellagic acid is formed whenever tannic, gallic, or pyrogallic acids are found in contact with the salts of silver, as well as with many other metallic salts in aqueous solution, and it is this body which principally forms the granulous deposits observable during the slow development of paper positives upon albumen and collodion.

We can ascertain the presence of this body upon freshly developed negatives with pyrogallic acid, by pouring upon the surface slightly heated nitric acid, which possesses the property of dissolving ellagic acid with a brilliant red hue which disappears shortly afterwards, because this substance is converted into oxalic acid.

An analogous reaction takes place upon fixing a slightly washed negative obtained in the same manner, with a solution of cyanide of potassium: a violet red hue is obtained, but it disappears almost immediately upon contact of the excess of cyanide. This effect is due probably to the first action produced being that of the potassa (which is always contained in great excess in the cyanide of potassium of commerce), upon the ellagic acid which this alkali dissolves, with the characteristic hue, as forming a salt of potassa insoluble in water, but nevertheless disappearing, in the present instance through the excess of potassa and of cyanide, which also probably modifies this little studied salt.

When the exposure in the camera is terminated, the plate is removed from the frame, in taking it by the upper left hand corner: the collodion surface is kept upwards and the lower corner always a little depressed by inclining the plate.

If the plate does not exceed the ordinary dimensions, 12 by 10, it may be developed while held in the hand; but when several plates must be prepared in succession, the fingers become fatigued, which can easily be avoided by placing the plate on a tripod or other suitable stand. We employ, for example, a large glass funnel, reversed, the pipe of which is enveloped in folds of tissue paper to hold the plate without slipping during the developing operation, or when we are obliged to incline the plate suddenly in various directions. In this manner almost the whole weight of the glass plate may be supported, and staining the fingers is avoided.

Beside, whatever be the means adopted to support the plate, it is placed over a large dish arranged for the purpose upon a high table placed opposite to a window furnished with a pane of yellow glass.

The plate is poised upon the pipe of the reversed funnel in the dish and kept in the position indicated: the side opposite the operator being depressed, and the solution of sulphate of iron is poured on at once.

This operation, apparently so simple, demands, nevertheless, a steady and dexterous hand: there is no particular way of arriving at the perfection of a skilful operator; but in covering at a single dash equally all over a large plate, held in such manner that the liquid is not divided into several channels, really demands much skill. The solution of sulphate of iron, according to the formula already given, must be poured at the moment of development into a glass vessel, the capacity of which is more than sufficient to contain the liquid intended to cover the plate.

The application of the sulphate of iron upon the exposed plate must be made, not by throwing, but by pouring the solution largely and suddenly, commencing at the corner held in the hand, and managing the operation so that the liquid spreads continuously, covering the plate at a single coup, and poured off at the opposite side, held slightly depressed for that purpose. Immediately the developer arrives at the extremity of the plate, the latter is raised so as to cause the liquid to flow back again, and so on con-

tinuously, giving the ferric solution a circular motion, so as to mingle it as intimately as possible with the nitrate of silver on the sensitive film and equalize the action, which, without this precaution would remain partial and occasion a development in the form of streaks or undulating stains arising from the different densities of the two liquids.

In the course of a few seconds the image will appear and gradually become developed; the sensitive film will retain its original aspect in those parts which correspond to the deepest shadows, while the impressed portions become clearly defined; the strongest lights will first appear, then the half tones, and finally the lightest tones and details. At this point the development must be stopped, to prevent the picture becoming fogged, and to retain all its purity. If it has not the desired vigour, as ordinarily happens, it may be strengthened by means of pyrogallic acid.

In this manner very beautiful negatives may be obtained, which give positives on paper very rapidly, and which furnish light proofs, the effect of which is much esteemed.

This phenomenon of the appearance of the picture under the action of the developer is the most interesting in photography; the strangeness, or rather the marvellousness, of this faithful and delicate apparition, by the contact of simple chemical solutions, will always excite the admiration of the attentive observer assisting for the first time at this stage of operations.

The development of the photographic negative is also the most important part of the manipulations, for it is that upon which the beauty of the proof principally depends. The essential thing in application is, that the developing solution poured upon the image covers it at once, and be rapidly and uniformly spread over it without being violently thrown upon it; on the contrary, this would be a very sure cause of failure, because the liquid in becoming divided will form air-bubbles, and be irretrievably lost. We pour the liquid on largely and without hesitation in making it as it were to glide over the glass plate, and flow to the depressed edge, giving such a motion to the liquid as to cause it to act uniformly upon every part of the picture in succession. If we neglect to make the liquid return equally and frequently upon every portion of the plate, there will be unequal intensity in the places avoided, which will be an irreparable defect.

The solution of sulphate of iron in contact with the nitrate of silver which impregnates the sensitive film, reduces the latter salt to the metallic state, and at the same time causes the image to appear; but when the solution becomes thick by this too prompt action, we drive it off the plate by a new coating of the liquid, which must not be encouraged if we desire to obtain pure and well-defined negatives.

It is frequently during this new contact of the sulphate of iron that the last details completely appear, but the picture rarely attains the intensity it ought to possess. To render it more vigorous generally, and in the dark portions especially, we collect in a glass measure the second portion of the sulphate immediately after it has spread all over the plate, and add to it some drops of nitrate of silver of 3 per cent. strength, to which a little acetic acid is added; in pouring the whole upon the plate, we make it cover anew all the parts of the picture successively, which thus acquire intensity. If necessary we repeat the operation, changing each time the thick solution for a fresh quantity of the developer.

Another means, very energetic and much more constant, consists in driving off, as before, the thick layer, arising from the first development, and allowing the greater portion of the excess of sulphate of iron to drain off, and to replace it by a solution composed of

Water	500 parts.
Nitrate of silver, crystallised...	18 "
Acetic acid	20 "
Alcohol... ..	15 "

The mixture is agitated for a few moments by inclining

the plate; then we pour on a third dose of the iron solution and allow the greater portion of it to flow off again, at the same time rapidly mixing the two solutions. The action is very energetic, the negative gains much in vigour, and it must be carefully watched so as to stop it in time.

This method, a little more expensive than the former, is very advantageous for large negatives, we employ it also for plates 12x10 which we can cover sufficiently with from five to seven ounces of the preceding silver solution.

We have in this manner obtained very fine negatives, soft and beautifully modelled, only the lighting must be appropriate, and also present a character of uniformity in the light tones as in the more luminous parts, which must, nevertheless, receive only very little direct light. We must not allow the solutions to remain too long upon the plate after they have begun to thicken, because they deposit particles of metallic silver which impair the purity of the picture.

In most operating-rooms another method, slower in its action, is practised, the superiority of which, however, is undoubted; it consists in first developing the image with sulphate of iron, exactly in the same manner as previously indicated, only we must take care to arrest the action of the developer as soon as the picture appears in all its parts, and before it has begun to fog: it is at this moment, if we clearly understand the process, that we can obtain the wished-for result by modifying the effect, if we perceive that the exposure in the camera has been too long, or not long enough, or the lighting badly distributed, &c. In fact, before going further, let us say that if the exposure, for example, has been exaggerated, it will suffice, to avoid the inconvenience which must necessarily result, to stop the development immediately the shadows are sufficiently brought out, without waiting the action continuing itself, darkening all the details in one uniform grey tint. If the contrary is the case we prolong as much as possible the action of the sulphate of iron to gain on the side of the shadows and light tones. The same thing takes place in an unfavourable lighting of the object; if it be too harsh, we continue the action of the developer a long time, in order to equalise the impression; while if it be uniform and without depth, we endeavour to preserve more opposition or contrast in the picture than it naturally possesses by stopping the reaction sooner than we should do in ordinary cases.

Returning to our own mode of development, let us say, that as we have stopped the coming of the image without any regard to its degree of intensity, we must communicate to it the vigour required for printing positives by means which, no longer developing the image, simply communicate to it more strength in the opaque portions.

To this end, after well washing the plate on both sides, to stop the action of the ferric liquid and remove the last traces of it, we effect the intensifying with pyrogallie acid, mixed with some hundredths of nitrate of silver in aqueous solution. Into a glass measure we put a sufficient quantity of pyrogallie acid prepared according to the formula previously given; then pour the liquid on the plate, in the same manner as with the first developing solution; but accidents being less liable to occur, it is not necessary to pour it on so largely or in so regular a manner. We keep the pyrogallie solution a few seconds upon the picture, and if there be reason to fear that the plate has not been sufficiently freed from the sulphate of iron, we reject the first layer and replace it by a second. In every case, while the solution covers the plate, we put into the glass measure a small quantity of nitrate of silver solution, and collecting the pyrogallie acid that flows off upon inclining the plate, the whole is immediately poured on to it.

We follow the action attentively by viewing the picture as a transparency, by lifting up the plate from time to time, from which we collect in the glass measure the liquid which flows from the lower angle. It is useful to repeat this operation often, by pouring on the pyrogallie acid collected each time in the measure. If this intensifying liquid becomes dark and muddy before the negative is quite finished, the

collodion plate is carefully washed under a stream of pure water, and the action may be continued with a fresh quantity of pyrogallie acid, to which must be added one or two hundredths of nitrate of silver, prepared according to the formula given above.

It is always good to wash the negative with pure water towards the middle of the operation of intensifying, because the pyrogallie acid becomes oxygenated during the reduction, it forms, as we have remarked above, even in contact with the collodion surface, a film, rendered greasy in its aspects by the acids, composed chiefly of insoluble ellagic acid, a film which opposes the contact of the liquid surfaces with that of the negative, which slackens considerably the effect, at the same time these impurities attach themselves more and more to the negative.

The picture should retain all its purity; under the action of the pyrogallie acid it acquires much vigour and relief, but it must not be carried too far. It is not the most vigorous negatives that yield the best proofs. We must, on the contrary, preserve a certain transparency in the darks, for there are shades in those parts as in all the others.

When the negative has arrived at the desired point, it is cautiously washed so as not to remove the collodion film from the glass, its adherence to which is greatly diminished after all these manipulations. If we provide a stream of water from a tap, we must receive the jet that flows upon the middle of the plate, and incline it in different directions to cause it to flow off the edges, so that we incur no risk of raising the collodion by the infiltration of the water at the sides of the plate, where it is always more or less detached.

The undoubted advantage of this process is, that it permits of stopping the development of the picture when it has arrived at a determined point, and in retaining the faculty of augmenting it afterwards to the degree of vigour desired.

The sulphate of iron appears to possess the remarkable property of completely destroying the effect produced by the light upon iodide of silver, as soon as it comes into contact with the latter; either because it destroys it by the reduction of the soluble salts of silver necessary to the sensibility, or from another cause, it acts in such manner, that the pyrogallie acid develops no detail, however weak it may be; be, its operation is limited to strengthening each of the parts already apparent by the metallic molecules which this organic reducing agent slowly liberates, and which fix themselves upon the various tones, in masses more or less considerable according to the extent of the first deposit effected by the sulphate of iron. It thus results that the entire image increases in intensity, or preserves a constant relation between its lights and shades, since the molecular attraction of the silvery particles is effected in the order determined by the luminous image, and the first reaction is exercised by virtue even of these lights and shades.

In treating of the development of collodion negatives, we have not thought of broaching a new subject, but we believe that the complete details of a good method of operating would be found very useful to many photographers. We have no doubt that the method we have here indicated is already more or less known; but when we see how few useful details are published in similar articles, we venture to hope that what we have written will be found of some service.—*Bulletin Belge de la Photographie.*

DRY COLLODION AND DRY PROCESSES.

BY DR. D. VAN MONCKHOVEN.

It is a common error to suppose that dry iodide of silver will not yield pictures in the camera. It is, nevertheless, certain that this substance yields very good results with albumen, waxed paper, and gelatinized paper; but in paper quite exempt from albumen and gelatine, and especially in collodion, iodide of silver sometimes yields pictures, and sometimes not.

We propose in this place to elucidate the cause of this fact.

A sample of recently prepared gun cotton is immersed in alcoholized ether, with which it is left in contact several hours; when it is dissolved, iodide of cadmium is added. We perceive that at first the solution becomes red, and then colourless, and remains so. (It is well understood that the gun cotton gives no acid reaction).

Cover a clean glass with such a collodion, sensitize the film, and carefully wash it with distilled water. Expose it to the light while it is still moist, then cover it with the developing solution mixed with nitrate of silver; a picture will be well developed, but quite fogged, without any intensity, and even when the exposure is prolonged the results are scarcely better.

If, instead of exposing the plate while it is moist, it is not exposed until dry, the same results are observed, but the picture is still more defective.

But if the gun cotton employed, instead of giving an amber-coloured collodion gives one that is bright red, then we observe a reverse state of things. Certainly, by washing with water the excess of nitrate of silver from the film after sensitizing, we remove from it a portion of its sensibility, and still more by leaving it to dry entirely; but the picture obtained is at least not veiled, and acquires great intensity under the influence of the developer.

There exists, then, a cause for the opinion admitted by some that collodion sensitized and simply washed will yield pictures, and also for the contrary opinion.

It is a very remarkable fact that collodions made with decomposed gun cotton, and old collodions, may be used dry without any preservative coating; and also, as a general rule, a good collodion (*i. e.* quick, and yielding not very intense images), cannot be worked dry.

The same thing applies to paper. Make use of a very pure paper, prepared with iodide of potassium and nitrate of silver. Wash it in water and dry it; no image will be obtained, or at least only a very bad proof. But if sized paper be used, then success results.

From this set of facts it results:—

1. That pure iodide of silver is incapable of yielding pictures.

2. That when in presence of an organic substance capable of combining with nitrate of silver, such as albumen, gelatine, resin, &c., it will, on the contrary, yield results when dry.

The proof lies in these two rules:—

A. When the collodion is new, as I have said, it does not ozonize the ether (that is to say, it does not liberate the iodine from the iodides), we shall then have, after sensitizing, a film exempt from organic matters, capable of combining with nitrate of silver, and *the image obtained in the usual manner will be entirely soluble in pure nitric acid.* The same result occurs with paper.

B. But when the gun cotton ozonizes the ether, it is because it contains a foreign organic matter; the same theory results when the collodion is kept a long time. The gun cotton is decomposed into matters hitherto unknown; but it is certain that there is no longer a simple solution of alkaline or metallic iodide, but rather a solution containing also an organic substance, capable of combining with nitrate of silver, and furnishing a picture independently of the iodide of silver.

The proof of this is, that a picture obtained in the ordinary way by the aid of an old collodion, and treated by nitric acid *does not wholly disappear*, the argentic-organic combination on the contrary remains, and *it is so much the more visible the more the collodion is decomposed.*

Moreover, take a good collodion, and employ it dry, with an exaggerated exposure. Then examine the plate, and *no picture will be visible*, just as if iodide of silver prepared in glass vessels had been used. (Washed iodide of silver does not blacken in the light.)

But take an old collodion, employ it dry, and the picture will become visible (at least in the high lights, corresponding with the darkest portions of the negative) on removal from the camera. However, this experiment proves that the

iodide of silver prepared by double decomposition, and well washed, does not blacken. *It is then quite evident that the picture is due rather to the organic matter.*

To operate with dry collodion, therefore, it suffices, according to this theory, to ascertain if the image disappears or not under nitric acid (after development), if traces of collodion remain, it can be employed dry, if not, it cannot.

Such is, in fact, the truth. The following is the method to operate with certainty in dry collodion:—Cover the plate with the collodion to be dried, sensitize the film, expose and develop either with sulphate of iron or pyrogallic acid. Wash in pure water when the picture has come out sufficiently, and cover the plate with pure nitric acid (this acid should remain clear after the addition of nitrate of silver). The picture disappears instantaneously. Remove the acid by immersing the plate for a few moments in water, then carry it into a full light.

Next examine the film attentively, especially in those parts which correspond to the sky or light parts of the model; with good collodions no image at all will be perceptible, but with those which have been made with bad or old gun cotton, or even old collodions, the images will be very perceptible, and the better the more the collodions are decomposed.

Collodions prepared with acid gun cotton do not give rise to this phenomenon, for it is sufficient to add an acid to the collodion; for the best prepared gun cotton decomposes slowly, both when it is dissolved and when it is kept in bottles. The newer it is the more the film is composed of pure iodide of silver, and the more it yields quick pictures; but the older it is the more it ozonizes the ether, the more organic matter it contains capable of combining with nitrate of silver, and the better it is suited for working dry.

To work with dry collodion, then, it suffices to add to the collodion a substance capable of combining with nitrate of silver. This is the purely practical side of the question, which we shall examine in our next article.—*Le Moniteur de la Photographie.*

* MICROPHOTOGRAPHY, OR THE ART OF TAKING ENLARGED COPIES OF PHOTOGRAPHS.*

THIS branch comprehends the mode of taking photographs of microscopic or almost invisible objects, as also of amplification by means of the solar camera. In either case means are resorted to by which light can be concentrated or condensed on the object or collodion positive to be copied and enlarged. These means are combination of plain reflectors, concave reflectors, double convex or plano-convex lenses. The appendages to the solar microscope and the solar camera are fac-similes of each other; but the solar microscope existed before photography had been elicited from chaos; the solar camera, therefore, is a mere imitation of its antecedent; the patentees of the latter instrument, then, can make claim to no originality of design; their only claim can be the application of the instrument to photography.

SOLAR MICROSCOPE.

The appendages to the solar microscope, that is, the condensing part of the apparatus, consists in the first place of a plano mirror in the form of a rectangle, whose width is at least equal to the diameter of the plano-convex or double convex lens which condenses the light received from the mirror. The length of the mirror must be about four times its width. At one end there is a hinge-joint, which allows the mirror to swing on the same like a door. The hinge is fixed to a circle of brass or other metal, which, by means of a dentated periphery, admits of a circular motion. By this contrivance it will be seen that the mirror has two motions at right angles to each other; for instance, supposing the back of the mirror faced the sun at noon, and were perpendicular to the horizon, then one of the motions mentioned would cause the mirror to incline towards the sun until finally it would lie flat on the horizon. The other motion permits the mirror to move either towards the East or the West; so that, as it now stands, if moved towards the West

* From *Humphrey's Journal*.

the silvered surface would face the rising sun; and, if moved in an opposite direction, or towards the East, the silvered surface would face the setting sun. By combining these two motions consentaneously, the mirror can always be so inclined as to reflect the rays of the sun from rising to setting into the axis of the condenser. The two motions in question are effected by means of screws and pinion-wheels, &c.

The part just described might be a concave mirror admitting of the same motions; this would act as a reflector and condenser at the same time. The condenser is fixed in the brass plate which is attached to the window shutter; and around the condenser the metallic ring moves to which the hinge of the mirror is attached. The object of this part of the apparatus is, by refraction, to cause the large bundle of parallel rays, that impinge upon its surface, to be condensed from a cylindrical into a conical form, so that, at a given distance this converging and condensed light will arrive at its apex or focus.

Now at this focus *all the light* that has passed through the lens will be concentrated, and at a variable distance before it arrives at this focus it will cover a variable space, varying from a point or zero upwards to an amount equal to the surface of the lens.

The amount of consideration will be the ratio between the squares of the distances from the focal point; thus suppose the focal distance be twelve inches, and that we intercept the cone of light at three inches from the focus; then by dividing the square of twelve by the square of three we obtain the ratio, which is sixteen, and this indicates that the light at this distance is sixteen times more intense than it was when it first emerged from the lens.

The object of the refracting lens, therefore, is to illumine the object with condensed light. If the lens be achromatic, the light will be white; if not achromatic, it may have spectral colours, of which some are useless in photography, whilst others are exactly those which are needed. Now the scientific optician can arrange his non-achromatic condenser in such a manner as to cover the object with the violet side of the spectrum by which means he draws an advantage from what otherwise would be a disadvantage.

The next appendage to the solar microscope is the *object holder*, which has a sliding motion to or from the condenser in the neighbourhood of the focus by which means the object can be placed in a condensed part of the cone of light which is just sufficient to cover it and no more; a contrivance by which light is economized.

The remaining part of the instrument is the microscope proper, which contains the corrected objectives for magnifying the object.

Now the above description is exactly the same as that of the condensing part of the solar camera. With such an arrangement of mirrors and refractors, the camera and screen may remain fixed during the whole time of the operation.

Another arrangement for concentrating the light is accomplished by means of reflectors fixed in the form of a frustum of a pyramid. But in the application of this contrivance, the camera and screens must all move together on a universal joint like a heliostat, by which means the silver surfaces of the reflectors can always be preserved in front of the sun so as to catch his rays.

The mode of using the solar microscope and the solar camera is in no wise different, excepting that in the former a transparent object is substituted in the holder for the transparent collodion positive in the latter. Each is placed in the cone of condensed light, in order to be brilliantly illumined, and in such a position in reference to the objective or photographic lens, that the rays of the picture coincide after emerging from the front lens with the rays of the cone of light. It is by this means alone that the best enlarged picture can be obtained.

HOW TO FIND THE POINT WHERE THE LENS IS TO BE PLACED.

It appears then that the lens may not be placed in any position for maximum effect; the true position depends upon the power of the condenser. To obtain the best results there ought to be a relative connection between the power of the condenser, the power of the objective, and the position of the object to be magnified. This connection not existing in any of our solar cameras, we must avail ourselves of what is next best, and fix our lens where we can obtain the maximum effect with given

materials. Take out the condenser, therefore, and ascertain the distance of its burning point. Measure this distance in inches and parts of an inch. Next take the front lens (which in this application is the back lens) of the camera tube and measure the distance of its burning point. Subtract one from the other, and the difference will give the distance nearly at which the black lens of the camera tube is to be placed from the condenser. For instance, supposing the focal distance of the condenser be sixteen inches, and of the back lens four inches, fix the latter lens at twelve inches from the condenser. In this way the cone of light from the condenser and the cone from the illumined object will nearly coincide, and will thus produce little or no interference.

Having once found this distance, adjust the tube accordingly and always use the same tube. The size of the diaphragm is not optional. It must be sufficiently large to admit the axis, at least of the peripheral pencils, otherwise those parts cannot appear in the picture; there must, therefore, exist an accurate connection between the size of the object, the correction of the lens, and the opening of the diaphragm; it is possible the combination will work respectably without any stops.

HOW TO TAKE AN ENLARGED NEGATIVE OF A MICROSCOPIC OBJECT.

Fix the solar microscope in the window-shutter of a darkened room. On a platform, constructed for the purpose, place a camera with an elongated bellows attached. The camera can slide between ledges nearer to or farther from the microscope. The axis of the microscope and of the camera coincide. The objectives that are most likely to give satisfaction to beginners are, the one-inch, the half-inch, and the quarter-inch. Insert the object in the holder. Bring the sun's rays, by means of the two screws on the brass plate, into the axis of the microscope. Let an assistant adjust the object into focus by bringing it nearer to the objective or withdrawing it from it, until the image is seen on the ground glass; this sometimes, and especially with a high power, is a very difficult task. When the image is once on the ground glass, let your assistant desist from all further interference excepting that of regulating the mirror, so that the sun shines continually through the object. By means of a microscope adjust the ground glass into accurate focus by sliding the camera. This adjustment is extremely refined; it requires the utmost care—the utmost precision.

When once attained, fix the camera, and see that no light can penetrate the camera excepting through the object glass. Withdraw the ground glass and insert the prepared plate for the negative, and draw out the slide for a short time. You have to find out the time of exposure by experience, so that the first attempt may be a failure. The development and fixing you already know how to manage.

By proceeding in this way the microscopist can prepare negatives of his choice specimens whereby he can obtain prints to aid him in the investigation of nature, much more accurately delineated than can possibly be accomplished by the aid of the camera lucida.

The solar camera is managed in the same way as the solar microscope, by adjustment on the shutter of a darkened room. But in this case no camera box is used. A moveable screen is used instead, on which the prepared paper is stretched on a plane at right angles with the axis of the condenser and the lens. A transparent positive is placed in the holder, in an inverted position, in order that the image on the screen may be direct. The rough adjustment to focus is obtained by moving the screen and the fine adjustment by means of the screw attached to the plateholder. The prepared paper, stretched on a board as if for a water-colour painting, is fixed exactly in the place of the focussing board, and then the cap of the tube is removed. The circle of light is kept in position by the two screws of the camera that move the mirror. The paper may have been prepared either with a chloride, as in the common contact printing process, or with an iodide or bromide, or both, as in the printing process by continuation or development, both of which will be described hereafter. To print by the former process and by means of the solar camera, is a very tedious operation, and will sometimes last several hours before a satisfactory picture can be obtained; by the latter, the process is very short, but the results are not so fine.

I need scarcely remark, what must already have suggested itself to the reader, that the shutter on which the instrument

is fixed has a southern aspect, in order that the photographer can operate from the rising of the sun to the going down of the same. The dark room, too, must be large enough behind the camera to admit a large screen, on which life-size pictures might be projected.

The one-fourth or the one-third tube is an appropriate size for the nine-inch condenser. If the diameter of the posterior lens in the tube were equal to the diameter of the condenser, and of equal focal length, the conditions prescribed above could not be carried out, and the dark room would have to be very large.

It is true that a large lens will produce a magnified picture of any object well illumined without adhering strictly to those conditions; but it is likewise true that the best results are obtained by using the same lens to amplify with which was used to obtain the original negative; and that the diameter of the transparent positive must be considerably less than that of the condenser, in order to obtain the requisite condensation of light upon it, which object could not be obtained if negatives were used that are in relative proportion with large tubes. Besides this, and which is the main point, a short-focussed lens that can perform the work required will perform it more quickly than a long-focussed tube.

A FEW WORDS ON PORTRAITURE.*

THE class of photographic portraits which is chiefly in favour at the present day, known as *carte de visite* or album portraits, make greater demands upon the photographer's knowledge of art principles in regard to composition and arrangement, than any other phase of photography has hitherto done, and this may render more interesting and important any hints which may lead to successful and satisfactory results.

Let it be remembered at the outset, that the mere delineation of an object, the mere production of a likeness, does not constitute a picture. To constitute a good portrait, and produce at the same time a pleasing picture, the model should be represented under such circumstances of position, arrangement, light and shade, and entourage of accessories, as shall indicate character, and at the same time be conducive to pictorial effect. The photographic portraitist labours under the disadvantage, that however perfect his taste, or knowledge of art, he has not absolute control, either over the forms he must delineate, or the relations of light and dark which shall exist in his model. He can, however, control the positions, and the light and shadow, so as to secure the most pleasing and characteristic lines these models possess, and he can by the selection and arrangement of his accessories secure the harmonious disposal of lines and of tones in his pictures; the liberal use of accessories now customary in photographic portraiture, permitting unusual facilities in this direction; but these should be used so as to secure unity and simplicity, harmony and breadth.

One of the first considerations in connection with portraiture, and especially where, as in card pictures, the full length of the figure is shown, will be as to position. This has much to do with the expression of character, as well as pictorial effect. Before speaking of the position of the model, a word or two in regard to the position in the picture, may not be out of place, as this affects the general result more than at first sight may be imagined. The figure should never, or at least very rarely, be exactly in the middle, or equidistant from each side of the picture; nothing is more formal or destructive of pictorial effect than such a position. As a general principle, more space should be in front of the figure than behind, unless some peculiarity of arrangement in the accessories suggest a different disposal. If the figure be placed equidistant from the top and bottom of the picture, it is still more destructive of suggestive truth, and pictorial effect, than if equidistant from the sides. The distant from the top and bottom is the chief means of suggesting the height of the

figure. The nearer the head is to the top of the picture, the taller the figure will appear; and the greater the space overhead, the shorter will be the appearance of the model. Where a series of portraits of a specific size is issued, as in the card portraits now common, a specific proportion might with propriety be adopted. These pictures are, for instance, generally about three inches and a half in length; on such a size a standing figure six feet in height might properly be made three inches high in the picture. If then, the remaining half inch were divided so that the feet of the figure were one-eighth of an inch from the bottom, and the head three-eighths from the top, a fair suggestion of the true proportions would be obtained. In larger portraits, especially busts, the position is not so important, but should still receive attention. A bust in profile, or three quarter face should have more space in front of the head than behind; a bust presenting the direct full face, may, however, without impropriety have the head equidistant from the sides.

The position of the model may be varied without limit; but it should be the aim to secure grace, and character, or both. Not less important than these in producing a satisfactory effect, is the presence of a purpose or object in the position. It is not intended by this to imply that the sitter should be in all cases engaged in some occupation, but care should be taken to avoid the suggestion of either entire vacancy, or the self-consciousness of having a portrait taken. In the portrait of a lady a variety of resources from this may be found; she may be examining a bouquet, arranging a vase of flowers, buttoning a glove, examining a picture, reading a letter, &c., &c. In the portraits of gentlemen, the same occupations would be less suitable; but others are available; even the conventional book held in the hand need not necessarily be arranged in the common-place conventional manner.

Entire repose is by no means inadmissible, but care should be used to secure the absolute feeling and appearance of intelligent repose, avoiding alike effort and vacuity. In all cases straight lines and angles should be avoided as much as possible in arranging the position. The figure perfectly upright, without inclination or curve of any kind is not graceful in any one, and in a lady is especially awkward and undesirable. The figure may lean against a column, a chair, &c., or in a variety of ways a little inclination may be induced, and curved flowing lines secured. In standing, the weight of the body should rest on one foot; this will secure a more perfect sensation of ease and balance than can possibly be obtained when the figure is supported on both feet. Whatever action may be desired in the model should not be secured at the expense of ease; there can be no grace or pictorial effect in the suggestion of an over-strained muscle or dislocated limb.

As regards the question of composition, the greater the simplicity the more perfect will be the result. Elaboration or complexity is undesirable at all times in portraiture, and in photographic portraiture especially so. It is, however, an important point, that a proper balance of lines, and of light and dark be secured. If all the lines in a picture tended in one direction, a most uncomfortable effect would be produced; or if all the objects or masses were accumulated at one side, leaving the other bare and empty, the result would be just as unsatisfactory. All pictures should have at least one principal light, to which all the rest is subordinate. This, in portraiture, is generally the face, upon which the chief interest is supposed to be concentrated. The light may be repeated in varying forms and more subdued degree, so as to carry them throughout the picture, a general principle of chiaroscuro requiring that some light should be carried into the deepest shadows, and *vice versa*. It is desirable, also, that the weight, or heaviest part of the picture, both in colour and form, should be at the base. Thus, the standing figure of a man unsupported by accessories, is very uncomfortable-looking; the picture requires a broader base; this may be secured by the

* From Newman's "Harmonious Colouring," by permission.

arrangement of accessories, or even by the simple resource of a stick or umbrella in his hand, placed at an angle with the body. The best effect is produced when the darkest masses are arranged at the bottom of the picture, as that also tends to the production of equilibrium or balance. Let it be distinctly remembered, however, that these and all other effects in composition must appear natural, and, of course, the artifice must not be seen. The veriest smatterers in art have an impression that the pyramidal form is the most satisfactory in composition; but it requires the skill of an experienced artist to secure the effect without obtruding the means.

Contrast is an important element in pictorial effect; contrast in lines, and contrast in tones. The value of curved lines will be best made apparent by contrasting them with straight lines; relief, vigour, and brilliancy are obtained by due contrast and variety of tones. Contrasts, however, should never be harsh or violent. Masses of black and white brought crudely together, without gradation of any kind, certainly produce contrasts; but without anything of pictorial effect. One of the most important qualities in a picture is *breadth*, of which crude and harsh contrasts are entirely destructive. The immediate juxtaposition of black and white draperies or accessories should, therefore, be as much as possible avoided. Both are necessary in a picture; but they should always be more or less graduated in their approach to each other. For this reason the background of a photograph is generally best of a middle tint, which does not contrast harshly with either dark or light draperies.

An important element in securing the harmonious contrast of tones is the judicious lighting of the model. By all means avoid a direct front light, which is destructive of all relief. Let the light fall on the model at an angle of about 45°; direct vertical light should be carefully avoided; side light may, on the other hand, be freely used. Direct light, it should be remembered, gives force; diffused light, softness. The best results are obtained by judiciously combining the two; direct light to give forms or contours, diffused light to give texture. Too much diffused light leads to flatness and tameness, by weakening the shadows. Some positive light and shadow are necessary to force and vigour.

In the small full-length portraits now fashionable, a variety of accessories and pictorial backgrounds are permissible. In the use of these, one of the most important things is the preservation of *keeping*, by the combination of such pictorial effects in the background, and such accessories only as are harmonious with each other, and with the character of the sitter. Nothing can be more ludicrously incongruous than the combinations sometimes perpetrated; the furniture of a drawing room apparently standing on the sea shore; a lady in evening dress standing amid Swiss mountains; a stolid old gentleman sitting amid vases, balustrades, &c., all wreathed with flowers. Or even when keeping is preserved in these respects, it is not uncommon to see gross violations of all possible perspective; objects in the background lighted from one side, whilst the model is lighted from the opposite direction, &c. It is not necessary, because a column, a curtain, or a chair are really good of their kind, and free from the common-place or vulgar in design and style, that they should appear in every picture; nor because a balustrade is real and well designed, that it should be obtruded in advance of the sitter. Variety is desirable in accessories, both as regards colour and form, so as to be readily able to meet the exigencies of composition. In using painted backgrounds, care should be taken that the light and shadow correspond with that on the model, and it is desirable to avoid designs such as foregrounds of tessellated pavement, which show, in a very definite manner, the exact direction of the perspective lines, and thus suggest one point of light for the landscape, and another for the figure. The carpet, or whatever may be used for the foreground, should be dark in colour, and not of a pattern too strikingly defined.

In grouping for portraiture, the small portraits of which we have been speaking permit the exercise of considerable

discretion, and render the task less difficult than in larger photographic groups. Fewer accessories are necessary for the purposes of composition, the balance of the picture being generally obtained by the arrangement of the figures. Variety may be obtained by the contrast of sitting and standing figures, by full face and profile figures, &c., &c.

These short hints and brief statement of general principles will, it is hoped, be found useful to many photographers.

DIALYSIS.

THE term Dialysis has more than once been used in connection with photographic operations in recent discussions. As it describes a chemical process, possibly not familiar to all our readers, we collate a brief description of its character. Dialysis was the discovery of professor Graham, who noticed that certain substances possess the power of diffusing themselves with great facility through water in comparison with others, and that they could be separated mechanically in solutions by proper appliances. Thus, suppose we take four deep glass vessels, such as long phials, and place in the one a few grains of common salt; in the second an equal quantity of sugar; in the third some gum; in the fourth dried albumen. Let each of the glasses now be filled up cautiously with water, and their contents allowed to stand until they are dissolved by the water. In watching the operations it will be observed that these substances gradually diffuse themselves through the water, but not all in the same period of time. The salt diffuses most quickly, then the sugar in about twice the length of time; the gum takes four times longer, while the albumen takes about twenty times longer. So different is the diffusive power of common salt and albumen in water—though both are soluble—that if the two substances, in equal quantities, are mixed together in water, the salt will completely diffuse itself through the water before the other is dissolved. Those substances which are crystalline are the most diffusive; those least so which resemble gum, glue and albumen. Professor Graham has given the names *crystalloid* and *colloid* to these two classes of substances. The crystalloids also possess the remarkable property of diffusing themselves through solutions of the colloids almost as rapidly as through pure water; while the latter do not possess this property.

A colloid and crystalloid in solution may be separated as follows:—Take a broad hoop, like that of a common wire sieve, and cover its bottom with parchment paper (treated in a peculiar manner with sulphuric acid) and float this vessel on clean water contained in another vessel, then pour into it a solution of common salt and albumen. In a short period afterward, the salt will diffuse itself through the parchment, and leave the colloid or albumen behind. In this way compound crystalloid and colloid solutions may be separated. The parchment vessel is called a dializer, and it has been applied to the examination of the human stomach in a person supposed to have been poisoned by arsenic, which is a crystalloid. The contents of the stomach were placed in a dializer, when the crystalloid passed through into the clean water in the under vessel, while the colloids, constituting the principal part of the food, remained behind. Dialysis may thus be usefully employed in a great number of cases of chemical analysis to facilitate operations.

Flint, which is one of the most insoluble of substances, has been obtained dissolved in pure water by the aid of the dializer. It cannot be dissolved in its natural state, but is first rendered soluble by a chemical process, then boiled in water and afterward separated by the dializer. Thus the flint is first fused with an excess of soda (or potash) which converts it into soluble water glass, or silicate of soda. It is now treated with hydrochloric acid, which unites with the soda and forms common salt. The latter is a crystalloid, the former a colloid. When placed in a dializer the salt solution passes through, while the silica is left behind, and

when it is allowed to stand for some days it assumes the consistency of glycerine and afterward gelatinizes into a solid form. It is stated that a solution of silica thus obtained exerts a peculiar action upon gelatinous tissues, such as skins, and converts them into leather.

No specific application has yet been made of the process of Dialysis to Photography, but it is important to photographers to have at least some slight acquaintance with such general chemical laws.

AERIAL PHOTOGRAPHY.

MR. A. SIMON, writing to the *Telegraph* on this subject, says:—

“Three different motions of the balloon and car concur against the steadiness required for photography, and for many useful philosophical experiments.

“1. The vertical motion, which alone does not alter the respective position of objects, and but very slightly their appearance, although it changes the scale of the photograph.

“2. The horizontal motion, which is sometimes very rapid, and must alter the impression taken.

“3. The rotatory motion of the balloon, combined with a certain independent rotatory motion of the car, which is, I think, the most injurious to the picture.

“These give for result a ‘moved’ or ill-defined picture; for the so-called instantaneous process requires a certain time for exposure, and steadiness of the apparatus is not needed during that time.

“Within certain limits, the vertical motion of the balloon may be checked; not so for the horizontal motion of a balloon carried with a medium moving at a high velocity. The picture must be taken when that speed is at a minimum, which is discernible by referring to some objects on the ground in sight.

“The rotatory swinging to and fro of the car might be obviated by joining each fastening on the ring to two points widely apart—say sixty degrees—on the circumference, where the nettings leave the balloon; or forming a continuous netting, with wide open mesh, down to the ring. The shape assumed, instead of being, as now, that of a cone tangent to the balloon, would be that of an hyperboloid, insuring a much greater stability and obviating some difficulties—such as the entanglement of the ropes; similar means being also taken to connect the car to the ring. The use of gyroscopes will be very advantageous to get a momentary stand-still for the lens.

“In ending, permit me to mention the experiment on aerial photography made in Paris some years ago by Messrs. Nadar and Godard. The balloon was fastened to the ground by means of ropes, notwithstanding which, or perhaps on account of which, instability was the cause of their failure in obtaining satisfactory results. They used to take impressions between two successive oscillations, but that time was not sufficient.

ANNUAL REPORT OF THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The Committee of the South London Photographic Society in presenting their Fourth Annual Report, are happy to be able to congratulate the members upon its continued prosperity. The meetings of the Society during the past session have been particularly characterised by their animated and cordial character, and the readiness with which photographic knowledge has been mutually exchanged. The various communications to the Society have been abundantly illustrated by the display of practical results, ingeniously constructed apparatus, and many pure chemicals and compounds. Although your Committee are unable to refer to any very marked or noticeable progress in connection with the art, yet they may notice with satisfaction that the various papers read under its auspices have conveyed the most recent and reliable information upon all subjects of interest. They regret that more zeal and attention have not been evinced in the acquisition of a better understanding of the physics of photography, and would urge upon all possessed of the requisite ability, perseverance in the study of those remarkable phenomena which are presented to observation in daily practice. They desire to express a conviction that a rich harvest of scientific truths is ready to be reaped from an

investigation of the causes of those “anomalous contradictions” which are continually recorded in the photographic literature of the day. They vain would hope that at the conclusion of another session to have equal reason to congratulate their brother members upon advances in scientific and theoretical photography, as they now have in connection with progress in the development of its practical and art capabilities.

Your Committee desire to tender their thanks to the gentlemen who have read communications to the Society and which have embraced papers on—

Subjects.	Names.
“Some Photographie Whimseys” ...	Mr. Leako.
“The Production of Prints on Resinized Paper and Silk,” and “Substitutes for Albumen” ...	„ Cooper.
“Instantaneous Photography” ...	„ Blanchard.
“Photography, its Retrospects and Prospects” ...	„ Fry.
“Rejlander’s Apology for Art Photography” ...	„ Rejlander.
“Thomas Sutton, B. A., on Art Photography” ...	„ Wall.
“Philosophy of Positive Printing” ...	„ Price.
„ “Double Printing” ...	„ Harner.
“Developing and Intensifying” ...	„ Leako.
“Fornic Acid in the Developer” ...	„ Cooper.

They have to congratulate the Society upon having been able to secure for each member copies of three excellent photographs, executed respectively by Messrs. Burn, White, and Rejlander. The ordinary pecuniary value of these, independently of other presentations to members, exceeds the amount of the annual subscriptions.

Since the last report, the South London Photographic Society’s Exhibition at Sydenham, has been brought to a successful termination, and the thanks of the Society are eminently due, and are hereby tendered to the Directors of the Crystal Palace Company, for their liberality in giving to each member free admission to the Palace during its continuance. Thanks are also due to the gentlemen of your own sub-committee who superintended the general arrangements.

Your committee have every reason to believe that the change of the place of meeting has been conducive to the convenience of members, inasmuch as they are assured that the communications with all parts of South London and the College are particularly expeditious and frequent. It has also been the means of enabling many gentlemen of eminence in art and scientific photography to join your ranks, and to take part in the ordinary meetings.

The out-door meetings of the Society have not been satisfactorily attended, and it remains for this meeting to decide as to the propriety of their continuance under official management, or whether they shall be left to private arrangements. The obstacle to their success arises from the necessity of having to appoint fixed days of assembling, and the chances against such occasions being opportune for photographic experiments.

The annual dinner at Dulwich during the vacation afforded every satisfaction, and although entirely apart from the superintendence of your committee, yet is gladly welcomed as a means of fostering the exchange of mutual good feelings, and personal reunion between the members.

It may be as well to state that the finances of your Society are in a satisfactory condition, and that a balance will remain in the hands of the treasurer after the payment of all liabilities. The subscriptions will in future be payable not later than on the second meeting of each session.

Signed on behalf of the Committee,
ALFRED HARMAN, Hon. Sec

Correspondence.

THE SALTS OF SILVER AND THEIR DEPARTMENT WITH ALBUMEN.

SIR,—You having inserted a letter of mine (March 27) on the above subject, I think, with your permission, this is the first place to recall attention to my “Theory and Practical Experiments on the cause of Insolubility on floating (well

prepared) Albumenized Paper on a Solution of Nitrate of Silver, viz., the Liberation of Nitric Acid." I now call attention to Emerson J. Reynolds' article on the same subject, page 251-2, *British Journal*, June 15th 1863, where that gentleman mentions the paper of G. Price, Esq., but does not notice the after discussion, wherein I mentioned my theory. Knowing the value of your space, I only mention the circumstances.—I am, yours, &c. J. W. HART.

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE annual meeting was held in the City of London College, on the evening of Thursday, June 11, the Rev. F. F. STATHAM, M.A., F.G.S., in the chair.

The minutes of a previous meeting having been read and confirmed, Messrs. W. W. King and W. Brown were elected members of the Society.

Mr. G. WHARTON SIMPSON exhibited a number of very fine specimens of heliographic engraving, by M. De la Blanchere, consisting of the portraits of public men. The exquisite perfection of the pictures as engravings would certainly suggest that the plates owed much to the retouching of the skilled engraver, but he was assured by M. De la Blanchere that these were quite untouched. The pictures were carefully examined and much admired.

Mr. SIMPSON also exhibited, as bearing upon the subject of the evening, a very perfect whole-plate picture, the negative of which was produced by ordinary iron development, without any intensifying with Mr. Blanchard's carte de visite collodion.

Mr. SIMPSON further exhibited Mr. Hughes's interiors of the bridal apartments at Osborne, taken on 10-inch plates with Dallmeyer's No. 1 triple lens, equivalent focus 8 inches. It might be interesting to add that views of the same interiors taken with the globe lens, of which so much had been said, absolutely included less angle than those with the triple. He also exhibited some specimens on enamelled paper, and on amorphous albumenized paper, by the Hon. Nassau Jocelyn.

The annual report of the Committee was then read and adopted (see p. 297). The report of the Treasurer, which showed a balance in favour of the Society, after paying for the three presentation prints of the year, of £8 2s. 2d., was also read and adopted.

Votes of thanks were passed to the officers for the past year and a special vote of thanks to Mr. Cole for the facilities he had kindly afforded the Committee for holding their meetings at his house.

No new nominations having been made, the officers already in existence, with the exception of the Secretary, were re-elected for the coming year.

Mr. HARMAN having retired from the Secretaryship from press of other duties,

Mr. SIMPSON said that he had good reason to hope that at the request of the Society, Mr. Wall, their former Secretary, by whose exertion the Society first came into being, and who had tended it with such assiduity in its infancy, would again accept the office of Secretary. He begged to move that Mr. Wall be again elected Secretary. The motion was seconded and passed by acclamation.

The officers now stand as follows:—

President.—The Rev. F. F. Statham, M.A., F.G.S.

Vice-Presidents.—Sebastian Davis, G. Wharton Simpson, and A. H. Wall.

Hon. Secretary.—A. H. Wall, Sherborne Villa, Dartmouth Park Road, Kentish Town, N. W.

Treasurer.—Noel E. Fitch, 13, Union Street, Borough.

Committee.—Messrs. Howard, Ackland, Blanchard, Harmer, Leake, Foxlee, Martin, and Newcombe.

The subject of open air meetings was then discussed, and it was agreed that open air meetings should be held fortnightly during the coming summer, cards with the dates and places of meeting of which were to be issued by the Secretary. An annual dinner to be held in July was also agreed upon. The particulars to be decided by a Committee and duly announced.

Mr. LEAKE then read a paper on "Developing and Intensifying" (see p. 280), after which

Mr. H. COOPER, Jun., read a short paper on "The Action of Formic Acid in the Developer" (see p. 279). Several negatives, illustrating the points referred to, were handed to the members.

After reading his paper,

Mr. COOPER made a few remarks upon some further experiments; in the course of which he stated that he found the difficulty of intensifying the image obtained by the use of formic acid was increased in proportion as the light was weak, and that the plate may remain for a longer time between sensitizing and developing, without injury, than with the ordinary developer. He also mentioned that the strength of pyro used was 2 grains to the ounce of water, and 15 minims of Morson's formic acid.

Mr. WALL, referring to a remark by Mr. Leake, to the effect that negatives might at times be too brilliant, said that the fact had often struck him forcibly. He had in his album many photographs which would be called by photographers good and brilliant pictures which were, nevertheless, bad likenesses. This he attributed to the photograph being too brilliant. He thought it would probably have struck other professional portraitists that brilliant pictures rarely pleased as likenesses. In some cases, of course, want of brilliancy would impair the likeness. He had recently coloured a solar camera enlargement, which was a soft and somewhat feeble picture. He carefully preserved every tone just as he found it; and having finally a sitting from life before he completed the picture, he was very much astonished to find it entirely unlike. This arose entirely from want of depth and force in the shadows. The face seemed flattened out by the weak shadows. When it was remembered that it was only by the nature and depth of shadows that forms could be indicated the importance of this subject would become very apparent. The shadows could be essentially modified also by the mode of printing, and printing either too deep or too faint might spoil the likeness.

Mr. COOPER had often noticed the fact to which Mr. Wall had referred. He had recently met with a striking illustration of the fact whilst copying a bust of the Princess Alexandra, a copy of which members had seen, and which possessed a very pleasant expression. By strengthening the shadows, however, the effect was entirely changed, and the face absolutely seemed to assume a frown. It was amusing how incapable many of the general public were of appreciating this fact. They seemed to have the impression that photographs must be like, must be true, although there were several good reasons why as likenesses they were often very far from being true.

Mr. SIMPSON thought that professional portraitists generally were very familiar with the fact that the degree of intensity in the picture must be governed by the nature of the subject; and the vigour of the negative, the depth of printing, and even the kind of tone must all be regulated by the character of the original. The delicately round features and tender shadows of a child or beautiful lady would not, for instance, be fairly rendered by a negative having the same force as that required for a strongly marked man's face, neither would it require printing so deeply. If the complexion were blonde it would not require either printing so deep or toning so black as if the complexion were dark. It had often been remarked that the sentiment of a picture largely depended on the printing and toning.

Mr. HOWARD, referring to development, mentioned a circumstance he had met with. He was using an iron developer, and added some citric acid. Thinking he had put too much, he added some ammonia to neutralise it, and to his surprise obtained no image at all.

Mr. DAVIS had met with precisely the same results on adding citrate of ammonia.

Mr. BLANCHARD had tried the same experiment with the same results.

Mr. S. DAVIS, referring to the subject of formic acid, said that at the time when Mr. Claudet announced such a great reduction of exposure as possible when using formic acid, he made some comparative experiments. He was using at the same time an iron developer containing 25 grains of iron and 25 minims of acetic acid. He used a bromo-iodized collodion. He found on testing pyrogallie acid with formic acid, that the latter required an equal or a longer exposure. It might be, however, that with a simply iodized collodion the result would have been different.

Mr. SIMPSON stated that he had recently had an opportunity of seeing Mr. Henry Claudet operate with the developer containing formic acid. He was altogether unprepared for the rapidity he witnessed. With a lens of long focus, a poor light, and almost all the blinds down, one negative was taken in two seconds, and another, with the blinds partially removed, was

only exposed one second. The images flashed out rapidly on applying the developer, and the requisite intensity was very easily obtained. So far as he could judge from the light in the first picture the exposure with ordinary bromo-iodized collodion and iron development would have been 10 seconds, and of the second about 5 seconds. He was altogether astonished at the rapidity. He had not yet had satisfactory opportunity of repeating the experiments. He thought one great source of error in repeating such experiments arose from the natural indisposition to begin *de novo*. Photographers were tempted to use the bath, collodion, &c., they had in hand, merely adding, at random almost, a little formic acid to the developer. If this did not succeed they voted the matter a blunder, and declared the process to be useless as an accelerator. Now Mr. Claudet laid great stress upon exactitude of conditions. The bath, collodion, and developer should all be just as he had described in order to secure success. (See details in our last, p. 277.)

Mr. SMARTT had experimented in the same direction, and with similar results to those which Mr. Simpson had just described. Indeed he could confirm exactly the relative exposures as conjectured by Mr. Simpson. Where ten seconds were required under ordinary circumstances, two were sufficient with pyro and formic acid. To secure successful results it was, however, imperatively necessary to adhere to the exact formula laid down. A bromo-iodized collodion should not be used.

Mr. DAVIS said although he had not succeeded, he thought there was unquestionable evidence of the fact that the exposure was lessened by the use of the developer. The portrait of Dr. Diamond which was exhibited, and which was produced in a very bad light in an incredibly short time, was evidence of that. He had used a bromo-iodized cadmium collodion.

Mr. SIMPSON was not able to speak positively, but he was inclined to the conviction that a potassium iodizer was important in this case. If a potassium iodizer, or a portion of that salt were used, he believed that a bromide might also be used. So far as his present experiments suggested, the bromide in this case gave immunity from spots, &c., without lessening the sensitiveness. He had used a simply iodized collodion, and one containing three grains of a bromide to the ounce, together with a potassium iodizer, and they were about equal in sensitiveness. If bromide of lithium were used, the iodide of potassium might be also used without danger of the double decomposition and formation of bromide of potassium, which generally occurred when bromide of cadmium was used.

Mr. COOPER had used a bromo-iodized collodion containing potassium, and the exposure with it was the same as with simply iodized collodion. With a commercial sample of bromo-iodized collodion the acceleration was not so great. He might mention that whilst a new bath gave the most sensitive results, yet with an old bath containing organic matter, which fogged with iron, pyro and formic acid gave perfectly clean pictures.

Mr. DALLMEYER said it might interest the meeting to know that Mr. Warren de la Rue used the pyro and formic acid developer in his astronomical photographs, and, as he had informed him, found the exposure reduced at least one-half by its aid.

Mr. HOWARD suggested that, as the subject was so important, it should be examined by the Experimental Committee.

After some further conversation, a committee, consisting of Messrs. Davis, Cooper, Leake, Smartt, Blanchard, and Simpson, were requested to examine the subject and open the winter session by a report as to results.

Mr. DALLMEYER then exhibited a camera for taking twelve small pictures on one plate. It was fitted with four portrait lenses of 1 $\frac{1}{4}$ -inch focus and 1 $\frac{1}{4}$ -inch aperture. These were made especially for Mr. Bennett for the production of stereoscopic portraits for a new patent stereoscope. They would also serve for the medallion portraits now produced by some photographers, but the best lens for that purpose was that which he made for Skaife's pistolgraph, which was the most rapid lens in existence, and was especially intended for small portraits.

After especial votes of thanks to the Chairman and retiring Secretary, the proceedings terminated.

Photographic Notes and Queries.

WHAT IS "A LITTLE?"

SIR,—Will you have the goodness to say what, in your opinion, constitutes "a little?"

I am induced to ask this question for the following reasons:

1st. Wishing to rectify a silver bath that had done duty for a long time, I obtained some oxide of silver and nitric acid, "prepared specially" by Mr. _____, of _____,

My instructions were to make the silver solution turbid with the oxide, filter the bath, and add a *little** of the nitric acid solution to every twenty ounces of the bath, with an assurance that it would be at once in a perfectly fit state for use. I followed the instructions—prepared and exposed a plate, which, upon developing, showed evident signs of having been excited in a *strongly alkaline bath*. So, thought I, more acid must be the remedy. I accordingly dropped more into the bath (three drops); tried another plate with a like result; and so I went on adding, drop by drop, until I found that some *thirty-six* drops were only beginning to render the bath in a state for use. Evening closed in upon me without my having been able to get a picture with clear shadows. I may add that the thirty-six drops of acid solution do not give the slightest indication of their presence by the litmus paper test.

Did I add too much oxide? there was considerable deposit on the filtering paper. I believe that Mr. _____'s nitric acid solution contains an infinitesimal quantity of the acid, and that it is inefficient for the purpose stated.

Am I right? or any other man, to pay two shillings for—having failed?

Add "a little"—

I have just opened Sutton's *Notes* of the 15th instant. On page 140, 2nd column, line 14 from top, he says, in reference to the acidification of a bath of thirty-five grains (which is the strength of mine), "add 'a little' acetic acid to it, say six drops to the ounce of solution."

Is he right, or —? to add 3 $\frac{1}{2}$ drachms of acetic acid to a bath of 35 ounces, and to call it "a little?"

In conclusion, will you kindly answer the following questions: 1st. In rectifying a bath can it be rendered too alkaline, thus necessitating a large addition of nitric acid to make it fit for use, or is an excess of oxide immaterial?

2nd. What amount of *acetic acid* should be added to a neutral silver bath to put it in good working order for "Hilshop's" dry process?

3rd. Should a bath acidified with either nitric or acetic acid give unmistakable evidence of its presence by the litmus paper test?

Apologizing for thus troubling you, I am, Sir, your obliged servant,

No. 1 to No. 249.

London, June 16th, 1863.

[The term "little" must always be understood in a relative sense, as it has no absolute and independent definition. Where it is used in giving formulae, it generally implies that the exact quantity is unimportant or undetermined, and that a certain discretion is permissible. The acid to which you refer is, we believe, made very dilute, in order that the addition may be easily graduated. In using dilute solutions, time is always necessary, in order to complete the necessary reactions between the agents employed; and with the acids in question it is probable that a result would be produced in a few hours not apparent in a few minutes. We should scarcely call six drops of acetic acid to an ounce of silver solution "little," but it may be regarded as little when compared with the thirty drops added to the aceto-nitrate bath used for Taupenot plates. In reference to your questions,

1st. Oxide of silver is very sparingly soluble in water or in the nitrate bath, only just sufficiently so to produce a very slightly-alkaline reaction. Under ordinary circumstances, therefore, the only result of adding too much oxide of silver is a certain amount of waste of silver, all excess being filtered out. A very slight trace of nitric acid is then sufficient to correct the alkalinity. But if a collodion containing salts of ammonium have been used largely in the bath, it will contain nitrate of ammonia, in a solution of which oxide of silver is soluble, and a sufficient amount might be dissolved to require a very much larger amount of nitric acid to neutralise it than you used. Although, under ordinary circumstances, the mode to which you refer is the most philosophical mode of rectifying a bath, and is generally successful, yet, for the reason to which we have referred, it is often desirable to use carbonate of soda instead.

2nd. We should say two or three drops to each ounce. If any trace of fog were present, we should add the acid until the fog disappear.

* Five minims the stated quantity.

3rd. If the litmus paper be properly prepared, it will show traces of any appreciable acidity, with either nitric or acetic acid; but we always prefer trying a plate to trying litmus paper. The exact amount of change in litmus paper is not a certain guide: trying a plate is.—*Ed.*]

Talk in the Studio.

THE ROYAL SOCIETY.—We have pleasure in announcing that Mr. William Crookes, whose name is well known to the readers of this journal, was recently elected a member of the Royal Society; an honour the more valuable because of the large number of candidates and the small number of those elected.

PLATE-CLEANING PREPARATION.—We have been for some time past using Werge's Plate-cleaning Solution, received from Mr. Hughes, of Oxford Street. It is the most efficient article we have used for the purpose indicated. The instructions on the label direct that the plate should be washed first and then finished with a little of the solution on a tuft of cotton wool. We have, however, used it without any prior preparation of the plate, whether new or old, old and dried films being removed by it with surprising ease, and a chemically clean surface obtained at once. We can strongly recommend it.

We have also tried for the same purpose a preparation in powder, to be used dry. It is entitled "Photographic Polish," and is prepared by Sanderson Brothers, of Eccleshall. It is applied with a piece of cotton cloth to the glass, without water or other vehicle. The plate must, of course, be freed from old films, &c., first. This powder then gives a good polish.

DOUBLE SULPHATE DEVELOPER.—Messrs. Beckett and Willis, of Scarborough, write:—"We enclose you a few more specimens of prints from negatives developed with the double sulphate of iron process as given in our letter about a fortnight ago, which appeared in your paper. We have received several letters since it was published, complaining that the persons that had tried it could not produce the same results. Two or three others wrote to us to thank us for the information, saying that they could produce beautiful pictures with it without any after strengthening with pyro and silver. This is a proof that those that did not succeed could not have used chemicals in proper condition as we have not the least trouble to produce good results in every case with less than half the exposure required for the old process with the ordinary sulphate of iron. You will be able to judge from the prints the class of negative they have been taken from. As a further proof of what we state we will send you one of the negatives to look at and you will then see the kind of negative it produces. These prints are toned with the same formulae that we gave in our last letter, chloride of lime and gold. Almost any tone can be produced with this bath: we have toned these few prints different colours to show what can be done with it on the new enamel paper; it may be as well to say that this paper was bought of Harvey, Reynolds, and Fowler, of Leeds, but we have several samples from other places that are equally as good as this." [The negative received is very fine indeed, at once soft and brilliant, and the prints delicate, vigorous, and of fine tone.—*Ed.*]

To Correspondents.

L. L. H.—The orange-flashed glass is coloured with silver and will resist actinic rays well. The brown pot metal may be used in a dull light, but not if full sunshine fall upon it. We do not know of any elastic dressing for woven fabrics, except solution of india-rubber or a varnish of boiled oil. Nitric acid has generally been regarded as injurious in a developer for negatives; but we are not sure that it is with good ground. In some recent experiments we found it gave great brilliancy, without injuring the intensity of the image. Good prints from your negatives are worth exhibiting.

ALPHA.—The lime bath is most favourable to the production of black tones. Use an intense negative, print deep, and tone until a little more than the desired depth of tone is required. By adopting this method you should have no difficulty in obtaining black tones.

CALX.—You are scarcely sufficiently clear as to the appearance of the stains of which you complain. Do they consist of dead white reductions of metallic silver? From your description it appears very probable that it arises from some kind of floating matter, or scum, on the surface of the silver solution. We have occasionally known stains arise from the use of a dipper which held a portion of the solution in its curve. To avoid such an annoyance, we prefer to use a dipper with a shoulder, instead of a curve; or if it have a curve, as many of gutta-percha or ebonite have, we pierce the bottom with one or two holes, so as to prevent it holding any of the solution. We see no reason to suppose that the fault is in your collodion.

AN OLD AMATEUR.—The stains in your prints are the result of partially imperfect fixation, arising most probably from the prints sticking together in the hypo bath, which was probably weak or old.

TYNESIDE.—You do not seem quite to understand the description referred to. The copying box described takes a plate 12 by 10; it is three inches deep from front to back, that is, there are three inches depth of wood in the frame. In the front end the negative is placed, and to the other end the flexible body is attached. When working this flexible body is attached to the lens. 2. The negatives are laid into the rabbit of the frame intended to hold them, and kept in position by a small hasp or turn button, which presses on the edge. A base-board of about three feet long will answer your purpose probably. That is if you use your quarter-plate lens, probably of about 6 inches focus, for the enlarging. If the box which holds the negative have a capability of extending to about 9 inches, and the camera to about 18 inches, that will enable you to enlarge two diameters. We do not remember the price of the box to which you refer. 2. If you added 10 grains of citric acid to 5 grains of sulphate of iron in an ounce of water, silver may be added freely without fear of decomposition. We have placed such a solution with silver added in sunlight for five minutes without any decomposition. 3. You obtain very clean pictures by washing and redipping. Clean pictures ought to be obtained without that trouble; but did you obtain any increase of sensitiveness?

T. H. REDIN.—The metallic spots on the paper, to which you refer, are a very serious annoyance; but we regret that we do not know of any means of avoiding them, nor of any paper which possesses certain freedom from them.

PIETROS.—One of the greatest difficulties in the way of giving exact formulae with chloride of lime, consists in the fact that it is a very uncertain compound, the amount of chlorine varying in different samples, and indeed continually becoming less with exposure in the same sample. There is no especial quality prepared for toning purposes, nor do we know of any advantage which would be gained if there were. Your prints exhibit a virulent form of meanness, most probably due to excess of chloride of lime. You should have used hot water in making the solution. In using the gold and carbonate of soda hot, coldness is the result of overtoning, and meanness the result of its over rapid action.

E. L., CHESTER.—We have never found that the prints toned by the lime bath reddened more in the hypo than those toned by other baths; but we have noticed that those toned in the lime bath, which look red when wet, often become very black on drying.

TYRO.—It is desirable, if possible, to have light from both sides in the glass room, but is possible, nevertheless, to obtain very good pictures in a studio lighted from one side only. The general design of your room appears good; you do not state the extent of glass you intend to have, but, judging from your sketch, we should think it desirable to have a little more, and nearly twice the amount of space overhead opaque.

K.—The prices of books, and other articles, are generally stated in advertisements, not in literary notices. The price of each number of "Adjutor," containing five photographs, is fifteen shillings.

J. SMITH.—Lamp-black and whiting, mixed with size or thin glue, in suitable proportion, will give a very good dark distemper background.

F. M. C.—Bromide and iodide of lithium are somewhat expensive salts at present. A few years ago we paid a guinea an ounce for some. They can now be purchased at about 8s. or 10s. an ounce. Possibly they may become cheaper if the demand increase. 2. Bromide of cadmium is of somewhat variable constitution, some samples containing more water of crystallization than others, and many samples containing a good deal of water mechanically combined. 3. Bromide of potassium is much more sparingly soluble in alcohol than iodide of the same base. 4. It is always desirable to allow collodion to stand for a day or two after iodizing, before use.

G. J.—Your cards look rough and coarse as you state, but it is chiefly from want of rolling. Get a rolling-press: there are several good and cheap ones in the market. The large ones of Bury, Brothers, are capital. One of the most efficient small ones we have seen is that of Mr. Jabez Hughes; it gives a surface almost rivaling that of enamel paper.

JARRETT.—The sentence in the work you quote, stating rapidity of action in lenses to be a matter of chance, is simply nonsense. The primary source of rapidity depends, other things being equal, upon the relation of aperture to focus; the larger the aperture and the shorter the focus, the more rapid will be the action of the lens. As a general rule, the largest aperture with which single landscape lenses can be worked is one-twelfth of the focal length, and a much better result can be obtained with an aperture half the size. Ordinary portrait lenses are generally made with their full aperture one-fourth or one-fifth of the equivalent focal length. Quick-acting portrait lenses have their full aperture about one-third of the focal length. In the lens used in Skiffie's pistol camera the full aperture is nearly equal to the focal length, and hence its great rapidity.

TROUBLE.—The negative collodion of the maker you name is, we believe, simply iodized. The spots and streaks of which you complain will probably disappear on adding a little of a bromide; say half a grain to each ounce of collodion.

R. P.—You had better adhere to the method you have found successful. The prints are very good.

S. T.—We cannot undertake commissions to select lenses. Our time is fully occupied with our own absolute duties.

AN OLD SUBSCRIBER.—We have not heard that a photographer has been sent out to Chili and Peru for the purpose of taking a series of photographs for the British Government. Several correspondents in our next.

FORMIC ACID IN THE DEVELOPER.

MR. MAXWELL LYTE calls our attention to the fact that we have, unintentionally, done him some injustice in the ignoring his claim to priority in the use of formic acid in the developer. We recently referred its first use to the Rev. J. Lawson Sisson, whose communication on the subject was published in the journal of the Photographic Society, in December, 1853. It was from seeing Mr. Sisson's communication that we first used formic acid ourselves, and we were under the impression that his was the first publication. We find, however, that three months prior to Mr. Sisson's communication Mr. M. Lyte had pointed out the advantages possessed by this acid in the developer. In the *Notes and Queries* of September 10th, 1853, a communication from Mr. Lyte appeared, from which the following is an extract:—

My developing agent is made as follows:—Take
 Distilled water 10 ounces
 Pyrogallic acid 6 grains
 Formic acid 1 ounce

The latter is not to be the concentrated acid but merely the commercial strength. These when mixed form so powerful a developing agent that the picture is brought out in its full intensity almost instantly, while at the same time all the deep shades are quite unaffected and the half-tones come out with a brilliancy I have never seen before.

Another excellent developing agent is composed as follows:—Take

Distilled water 10 ounces
 Sulphuric acid 3 drops
 Protosulphate of iron ½ ounce
 Formic acid 1 "

The formic acid is also a most capital addition to the proto-nitrate of iron, and either this or the former liquid produce most brilliant positives, leaving a fine coating of dead white silver.

A similar communication, dated August 19th, appeared in the *Photographic Journal* published on September the 21st, 1863.

We have much pleasure in making this rectification, the more so, that, whilst many valuable contributions to the progress of our art have been made by Mr. Lyte, this is not the first time his claims to priority in processes to which he has given origin have been unfairly overlooked. So far as the use of formic acid is concerned, we are glad to be able to rectify the matter at once.

Writing at the present time on the subject Mr. Lyte adds:—

The only reason which induced me to abandon the use of formic acid possessing as it does most manifest advantages, especially as a developer in *dry processes* or where light is deficient, was the variable strength and impurity of the commercial product of that day, and indeed the difficulty of obtaining it at all. Then pure acid being then only known as a curiosity in the laboratory. Now, however, with the improved methods of manufacture, I have no hesitation in recommending its use as being decidedly advantageous and it is even possible that if

made on a large scale, it might be found cheaper than acetic as well as being superior to it in other respects.

We fear that the difficulty to which Mr. Lyte refers is still largely in existence. Formic acid is, unfortunately, as sold commercially at the present time, a very uncertain and indefinite preparation, in many instances abounding with impurities, and, when pure, of uncertain strength. One eminent manufacturing chemist with whom we had some conversation on the subject, expressed a conviction that it was to the presence of some of the impurities generally present that much of its value as an accelerator was due, and that pure formic acid would be very similar in its action, when added to the developer, to sulphuric acid applied in the same way. Another chemist who has been experimenting in this direction, expresses his conviction that it is to the pure acid the advantage must be attributed. A sample, stated to be quite pure, gave, in Mr. Claudet's hands, excellent results, when used in much less proportion than he commonly employed.

But the term pure is unsatisfactory, unless we have at the same time some information as to the true proportion of acid contained. With a pure sample of acid of a definite strength, it would be merely a question of careful experiment, pursuing the exhaustive process, to establish a definite formula, which might be relied upon as uniform in its action.

The *rationale* of the alleged action is plausible. Formic acid is, in itself, at once a reducing agent and an acid retarding reduction. This anomalous combination of qualities is thus explained. On those portions of the plate upon which the light has acted it aids reduction; whilst on the shadows, upon which light has not acted, it exerts its acid action, retarding the reduction of the free silver, and preserving them perfectly clean. This latter is a quality especially apparent, the perfect cleanliness of the shadows, even when the development is considerably pushed. That it is an accelerator, when the proper conditions are secured, there can be little doubt. We have not yet had opportunity of preparing everything *de novo* for a series of satisfactory comparative experiments; but such additional experiments as we have been able to make have been unquestionably in its favour. The exposure in our hands continues to be about the same as for iron development, but yielding an especially clean, brilliant, and delicate negative with fine half-tone, dense lights, and in the deepest shadows no more deposit than bare glass. The colour of the negatives by reflected light is unusual, the image showing as a positive having lights of a bluish or steely grey. The collodion which has given us best results, contains about equal parts of the iodides of cadmium and potassium and bromide of lithium. With simply iodized collodion the time of exposure is about the same, but the negative is not so clean, occasional small spots and comets being apparent. With some other samples of bromo-iodized collodion, the exposure is similar, but the image is thinner than with iron. We tried it with one sample of collodion

which we should have expected to be useless. It was a sample, prepared by Mr. Sutton at King's College about two years ago, simply iodized with iodide of sodium. The bottle was about half full and had become quite red. The ether having nearly all evaporated, we added about an equal bulk of simply iodized cadmium collodion to thin it. This mixture gave us, with formic acid, equally rapid results as with a comparatively new collodion. We believe that the subject is one which will repay careful experiment.

DR. KEMP'S DESCRIPTION OF CERTAIN DRY PROCESSES.*

The true theory of the dry collodion processes, remains but very little understood. We are in the dark as to the precise channel into which effort for a perfect dry process should be directed. We are in the dark as to the exact cause of success in many of the processes which are found in practice more or less satisfactory. We are uncertain whether the action of the various preservatives in use is chemical or simply mechanical. "If we can but determine laws," Dr. Kemp observes, "the knowledge of the extent of their operation and the phenomena arising therefrom, becomes a mere question of *time and work*." But in the matter before us, the great difficulty is to determine laws. We have a large number of facts upon which to generalize, but they are not sufficiently specific in their bearing to lead to certain conclusions. Some excellent authorities have maintained that the presence of an organic salt of silver was necessary to success, and have therefore referred the value of the various preservatives applied, to this power to supply the necessary organic element. On the other hand, Dr. Hill Norris, unquestionably one of the ablest authorities on the subject, entirely ignores this theory, and states the value of the various preservative agents to depend upon their power to maintain certain mechanical or structural conditions of the film. Almost all the known facts on the subject may be used to confirm either theory. Again, rapidity in dry plates has been held by some to depend upon the preservation in the film of a certain portion of free nitrate of silver. Dr. Hill Norris on the other hand states that he has been able to eliminate from his extra sensitive plates every trace of free nitrate, without in any degree impairing their sensitiveness.

Dr. Kemp does not undertake in this pamphlet to enter into the theoretical department of the research to which it is devoted. His work is rather a record of experiments with certain practical deductions therefrom. He remarks, however, in his preface that the *rationale* of the dry processes will, he believes, be deprived of much obscurity by recognizing certain principles which he lays down. We will quote and leave them to the judgment of our readers:—

Two classes of sensitive surfaces exist, to one or other of which we may refer all the processes which come under the domain of photography.

1. We have a surface so prepared that, having been exposed to the influence of light, the iodide of silver remains in a quiescent state, until stimulated into action by a developer; to this class belong the usual wet collodion and most of the dry processes.

2. In addition to such a surface, we introduce a substance which not only places the iodide of silver in a condition to be acted upon by a developer, but initiates the action during the exposure of the surface to light. The Talbotype paper and dry tannin processes of Major Russell are instances of this latter class; and the methods proposed in the following chapters will illustrate both of these divisions.

We glean from Dr. Kemp's pamphlet that he is an ardent experimentalist, and in this little work his object is rather to make known certain modifications of existing processes, which have given him good results, and to suggest his view of the causes, than to propose anything essentially new. He describes four processes, each of which have their especial advantages and degrees of sensitiveness.

The first process is the malt process, with some slight

modifications in detail. Plates prepared by this process, he finds, require an exposure, varying with the nature of the subject and state of light, of from a minute and a half to two minutes, with a stereoscopic single lens with quarter inch stop.

The second process consists in the use of a mixture of tannin and malt. The exposure for plates by this process, under the same conditions, he estimates at one minute.

We may remark upon this by the way that the author states he was not aware that any one else had tried such a mixture until he saw an allusion to its use by Mr. Fassett at a recent meeting of the Philadelphia Photographic Society. Its use had, however, been described nearly two years anterior to the allusion in question. In July, 1861, we received from Mr. Penny, of Cheltenham, a couple of very fine photographs, the negatives of which were produced upon plates prepared with tannin and malt, the details of which were published in our pages at the time. Since that time, we believe, Mr. Penny has used the process with great success.

The third process consists in the use of a mixture of tannin and glycerine. The exposure under the same conditions as the others is estimated at from thirty to forty seconds.

The fourth process consists in the use of tannin, glycerine, nitrate of silver, and formic acid. The time of exposure has not yet been satisfactorily determined, but it is estimated at from fifteen to twenty seconds.

In regard to the first—the malt process—the author states that on its first announcement he was predisposed in its favour, for the following considerations:—

All the substances which play an important part in the production of the photographic image are either aggregate forms, the molecules of which are held together by very slight chemical affinity, or they are the derivatives of such; and it would be difficult to name a substance in which these two properties are more remarkably united than in the case of malt. We are acquainted, for instance, with a variety of substances, differing widely in their appearance as to physical characters, but all comprised between the limits of the formula, C₁₂ H₁₉ O₉, and C₁₂ H₁₄ O₁₄ differing, in fact in elementary composition only as the quantity of the elements of water which they contain; thus, dextrine, or British gum, C₁₂ H₁₀ O₁₀, only differs from starch C₁₂ H₁₉ O₉, in containing the elements of one equivalent of water; cane sugar C₁₂ H₁₁ O₁₁, in containing the elements of two equivalents of water; crystallised sugar of milk, C₁₂ H₁₂ O₁₂, in containing the elements of three equivalents of water; and so on to the sugar of fruits, C₁₂ H₁₄ O₁₄, which contains the elements of five equivalents of water.

Now malt contains, not only the radix of this series—*starch*—which is capable of being thus transformed, but it contains, in rich abundance, this radix actually transformed into some of the substances above alluded to, but pre-eminently disposed to still further disintegration, from the very circumstance of its containing within itself the catalytic body which, above all others, effects these changes with infinite rapidity, and, for that reason, called *diastase*, with such energy, moreover, that a single part of this substance is capable of converting 2000 parts of starch, first into dextrine, eventually into grape sugar. Certain conditions, indeed, are necessary, and these are generally supposed to be very simple, but are, in fact, mightily effective engines in all organic changes—*heat and moisture*. Nor will it escape observation that two of the substances above mentioned, gum and grape sugar, are familiar to us as agents employed from the earliest days of photography, grape sugar especially, as what was supposed to be an accelerator, and, at one time, much recommended in the wax paper process—an accelerator certainly in one sense, as the writer can testify, for it has a marvellous tendency, in slow development, to produce excessive action in the developer and to cause the silver to be deposited, not only on the points acted upon by light, but over the whole surface, thus destroying the purity of the whites and damaging, if not spoiling, the negative. Again, collodion itself is the derivative of a body, *cotton*, closely analogous in its chemical composition to starch, and coming within the series of compounds to which we have alluded: analogy, then, was not urged beyond its legitimate bounds in suggesting that the powerful catalytic body, *diastase*, might, even in collodion itself, effect a change highly conducive to initiating or accelerating changes in the iodide of silver under the influence of light.

The process, as described by its propounder (Mr. Maenair), did not, however, yield in Dr. Kemp's hands satisfactory negatives—they were thin and deficient in vigour. Still impressed with the theoretical considerations in its favour, which we have quoted, he proceeded to further experiments, and at length arrived at satisfactory results. We subjoin the details of what he distinguishes as the

First Process.

Take two ounces of malt, crushed in a mill, and break it up still further by passing over it several times an ordinary roller, such as is used for making pastry; pale malt should be preferred, because in high-dried malt much of the starch is converted into British gum, and a very viscid infusion is produced, not adapted to the purpose contemplated. Place the malt, thus bruised, in an earthenware jug, or any other suitable vessel, and pour on it, by degrees, two fluid ounces of lukewarm water, with constant stirring, and

* A Description of Certain Dry Processes in Photography, especially adapted to the use of the Tourist, with Supplementary Notice of Plans useful to the Scientific Traveller and Misjourner. By George Kemp, M.D., St. Peter's College, Cambridge. London: J. W. Davies.

let the whole be kept in a warm, but not hot, place for a quarter of an hour, a cool kitchen oven answers the purpose well; in the meantime raise eight ounces of distilled, or, at any rate, pure rain water to the boiling point, and pour it on the malt, soaked as above, constantly stirring; cover the vessel and return it to a warm situation, and thus it may be left for two hours, by which time the fluid will have entirely changed its character and become sweet; it may now be allowed to cool for an hour, and then the whole contents of the vessel should be emptied on a canvas or hair strainer, a common sieve in fact, and, when the fluid has run through, a couple of ounces more distilled water should be quietly poured on the pasty mass, and thus the infusion which it retains will be principally removed by displacement. It is very important to pay attention to the quality of the water, and negligence in this respect has in more than one instance led to the rejection of this process; of course, if chlorides or carbonates be contained in the water, which is almost invariably the case with ordinary hard water, the plates, when treated with the preservative fluid, will necessarily be rendered insensitive from the formation of chlorides or carbonate of silver, in the original plan; and the subsequent preparation, however, of the preservative fluid, by the writer's method, will prevent the possibility of the latter salt being formed. On resting for a short time, the strained fluid will have deposited a thick sediment, from which the clear supernatant fluid should be poured; it is not necessary to filter it, which is a very tedious process, and with the quantities above proposed, fluid enough may be poured off to coat three dozen stereoscopic plates. Pour the fluid, thus obtained, into a Florence flask, or such vessel, add ten drops of glacial acetic acid, agitate, place the flask in a water bath and raise to the boiling point, retaining it at this temperature until the fluid in the vessel boils well, it may then be allowed to cool. As it cools, we shall again find a fluid sediment, which, as above, may be separated by decantation; add half an ounce of alcohol and the preservative fluid is prepared, requiring, however, in most cases to be strained, though it is useless to filter it, as, even when passed through a filter, it will retain its milky, emulsive appearance, which is no detriment and cannot be removed, excepting by a circuitous, complicated process, and we all know that it is essential in photographic operations to keep the conditions as simple as possible. The subsequent steps are those common to all prepared plates, that is to say, the film of collodion is sensitized in the nitrate of silver bath, and thoroughly washed with distilled, or, at any rate, pure rain water; the preservative fluid is then poured upon it repeatedly and in such a manner as to ensure its action upon every portion of the surface, and then, deviating from the directions of Mr. Macnair, the plate is introduced into a dish of soft water and allowed to soak for five or ten minutes; it is again washed with a fresh supply of water and placed in a suitable position to drain, resting one corner on blotting-paper. In the course of half an hour it may be exposed to heat in any suitable manner in order that it might become thoroughly dry; the plate, in fact, should be heated to such a degree as the hand will just bear, and may then be stowed away for use.

Plates prepared by this process, and rigidly secluded from light, damp, and foul air, are stated to keep for at least six weeks.

One of the especial characteristics of the malt process was observed to be the tenacity with which it adhered to the glass, and it occurred to the author to utilise this quality in the tannin process in which the greatest trouble is the tendency of the film to leave the glass. After a variety of experiments, which are detailed, the following was determined upon as the

Second Process.

- "1. Having prepared malt infusion and strained it, add one-third bulk of alcohol. Leave to deposit, and filter.
- "2. Just before using, add an equal bulk of solution of tannin in water, five grains to the ounce, and again filter."

This solution was used in the usual way, and from the extracts which the author gives from his note-book, we learn that plates kept two months give good results. We may here note in the author's experiments a somewhat unusual one, which is however stated to be successful, a tannin plate is re-dipped in an aceto-nitrate of silver bath before developing.

The author was anxious, however, to obtain a greater degree of sensitiveness without any sacrifice of other good qualities, and bearing in mind the theoretical considerations which had predisposed him in favour of malt, he looked for another body "not only produced from others by changes easily effected, but in itself so nicely balanced as to the forces which keep its molecules in a state of aggregation, that these can be disturbed and assume new forms by apparently trifling causes." Such a substance he found in glycerine, and by its aid, after various experiments, he was led to the

Third Process.

"The preservative solution for the tanno-glycerine process is thus prepared:—

Solution A.	Tannic acid	30 grains
	Water	1 ounce
	Glacial acetic acid	5 drops.
Solution B.	Glycerine	1 drachm
	Solution A	2 drachms
	Water	5 "

which latter is poured on and off the plate in the usual manner adopted at

this stage." The addition of acetic acid was made in consequence of slight fogginess observed on certain portions of the plate during development, and it certainly remedied the evil; but the bath was in fault, as it gave foggy results with the wet process.

The author refers to this process as giving very good results for interiors, and gives an extract from his note-book to the effect that the two halves of a stereoscopic plate had respectively ten seconds and twenty seconds exposure in his drawing-room with a Dallmeyer's stereoscopic lens, No. 4 stop, on a dull day in December; both halves coming out with long development.

The next process is stated to promise very rapid results, but requires great care in its management. It is called

Fourth Process.

The tannin and glycerine are used as before, with the addition of ten minims of formic acid to each ounce of the preservative solution, and when well mixed, which, of course, must be at the time of using, ten minims of solution of nitrate of silver, strength twenty grains to the ounce; the quantity of the two last fluids may be increased to thirty minims of each; but most extraordinary care must be taken thoroughly to wash the plates. Let it also be observed that formic acid of the strength used by the writer, which is the strongest and purest he can obtain, has a great tendency to loosen the film bodily from the plate.

Plates by this process have not been kept more than a day.

With regard to the collodion to be used with these processes, Dr. Kemp expresses a conviction that any good bromo-iodized collodion will answer, but he gives a formula, for which we refer our readers to his book.

The nitrate bath is prepared as follows:—

- A. Re-crystallized nitrate of silver 320 grains
- Distilled water 5 ounces.
- B. Caustic potash (avoid ammoniac) 2 grains
- Distilled water 1 ounce.

Mix these, and, when agitated, allow the precipitate to subside, and filter; fill up to nine ounces and add acetate of soda, previously dissolved in an ounce of water, three grains with five minims of glacial acetic acid. The bath is now ready for use, and should be tested for action with a wet collodion plate, developing with pyrogallie acid. If foggy, more acetic acid should be added, drop by drop, until the bath works clear; but the writer has always found the above proportions give good results. It will be observed that the bath is not, as usual, saturated with iodide of silver; the first plate may suffer a little if the weather be very warm, but it is simpler and safer, for reasons which will presently be stated, to leave it thus.

The washing and drying may be carefully conducted in the usual way; but the author enters into minute details, both in regard to these and other manipulations, describing the methods most successful in his hands.

For development he prefers the slow method with gallic acid, strengthening if necessary with pyrogallie acid and silver, or by some other of the known intensifying processes.

In regard to the class of negatives produced we may say that at a recent meeting of the North London Photographic Association, the chairman exhibited some of Dr. Kemp's negatives, which were very excellent in quality, but by which of these processes they were produced we cannot state.

Besides the full details of the processes of which we have given a copious synopsis, there is much incidental valuable information in the book. It is remarkably free from dogmatic assertion or egotistical claims, and is written in a winning courteous spirit, well worthy of imitation. The chapter on Photography for the Scientific Tourist and Missionary, is devoted largely to the consideration of the methods of securing portability, the use of either the collodion process, on mica plates, or of the Talbotype process being recommended.

Critical Notices.

A POPULAR TREATISE ON PHOTOGRAPHY, translated from the French of Dr. VAN MONCKHOVEN, by W. H. THORNTON, Ph. D., F.C.S. London: Virtue Brothers.

THE original of this work consists of an excellent epitome of the author's *Traité General*, compiled by two gentlemen, and corrected and endorsed by Dr. Van Monckhoven. The English edition is a free translation, with elisions, additions,

and modifications, by Mr. Thornthwaite. It is most profusely illustrated with engravings showing the forms of apparatus, or various methods of operating. We cannot entirely endorse all the ideas of the author, either as to processes or modes of operating, but we can recommend the work as a very complete, clear, intelligent, and, on the whole, trustworthy manual, leaving very little untold which ought to be stated in such a work, and stating still less that may not be followed with exact precision. This translation forms one of a series of rudimentary manuals originally published by Weale and Co., but now by Virtue Brothers.

CARD PORTRAITS, by Mr. Sarony, Scarborough.

WE have received from Mr. Sarony a handsome album of card portraits, amongst which we find some of the choicest gems we have seen. They are, for the most part, printed on enamelled paper, upon which a marvellously rich tone is obtained. The photography and the artistic taste are, in all cases, good, and, in some, perfect. As regards the photography, the pictures are all exceedingly brilliant, and the majority exquisitely soft and delicate as well. The definition is admirable throughout, although from the ease of expression in all, they would appear to have been taken with very short exposures. The lens, we understand, is Dallmeyer's No. 2 B. One of the especial features which strikes us is the easy, graceful, and natural posing, as well as the variety of effects, and absence of the common-place and conventional.

We have one striking illustration before us of the art power of photography. It consists of the portrait of a lady by Mr. Sarony, and another of the same lady by another person. The latter presents a somewhat common-place, coarse, plain-looking woman; the former a pleasing, graceful portrait of a lady. One is angular, hard, and square; the other is soft, delicate, and pleasing, if not beautiful. There are some of the pictures in this album, which, from the beauty of the model, the sweet expression, and graceful pose, the rich and well arranged accessories, and perfect photography, are amongst the choicest gems we have seen of photographic art. The frontispiece of the album is a clever idea, which, possibly, some others of our readers will be tempted to imitate. It consists of a card picture with a pleasing design, and made by the arrangement of card portraits. A pair of inverted cornucopias form an arch at the top; from these are flowing, on each side, streams of card pictures arranged in good lines. A medallion portrait of the Queen, and the address of the photographer, are in the centre. A neat border, formed of card portraits cut into ovals, runs round the outside. The effect of the whole is so good that it will readily find a place in any album, where it becomes a capital mode of announcing the name and address of the photographer.

A NEAT MODE OF WASHING SENSITIVE PLATES.

ON a recent visit to the studio of Mr. England, we were pleased with a very neat and simple contrivance which he used for washing sensitive plates, both during the preparation of the plate for a dry process, and also during the development of negatives produced on dry or wet plates. The method to which we refer has the especial advantage of being easily contrived by any one, and of being as inexpensive as it is efficient. It consists of an india-rubber tube attached at one end to a vessel containing water and having at the other end which hangs down an American clip. A hole sufficiently large for the tubing to pass through is made in one limb of the clip, the tubing is then pushed through so as to project about an inch beyond the biting end of the clip. The tube thus compressed, as by a spring tap, is quite water-tight when hanging at rest. When required for use, the slightest pressure opens the clip sufficiently to allow the water to pass through in a gentle stream, largely under

the control of the operator. The following outline sketch will make the matter more clear.

It will readily be seen that a very efficient washing can be given to the plate, with very little danger to the film, by using this contrivance. The stream can be directed on to any part of the plate at the will of the operator without approaching the edges or tender parts of the film. The fall of water from a tap often proves fatal to delicate films, and the use of a jug is troublesome. To those amateurs whose supply of water in the dark room is limited, the plan will be found a great convenience, as by the careful and slow application of a gentle stream of water a more efficient washing can be given than by the hasty and uncontrolled flow of three times the quantity. The simplicity and cheapness moreover, of the contrivance recommend it for a trial.

Scientific Gossip.

EBULLITION OF WATER—BUMPING—AFFINITY OF WATER FOR DISSOLVED GASES—OXYGEN FROM BROMINE—DECOMPOSITION OF WATER BY HEAT—POSSIBILITY OF SEPARATING NITROGEN FROM WATER.

IN boiling water in a test tube every one must have noticed that the phenomenon does not take place with uniform regularity. Numerous small bubbles rise from the heated part of the tube as the temperature approaches the boiling point, and that being reached ebullition proceeds for a brief time without any noticeable occurrence; soon, however, the bubbles of vapour rise from the bottom of the tube at longer intervals until at last the general character of the boiling liquid has the appearance of a perfectly quiescent tube of water affected at distant intervals with sudden and violent burst of vapour which have an almost explosive energy. The different phenomena here described attracted the attention of Mr. W. R. Grove, F.R.S., about sixteen years ago, and he has lately given before the Chemical Society an account of some very curious results at which he arrived in the course of this investigation. Some very remarkable observations on the ebullition of water were published many years ago by Professor Donny, of Ghent, and it was these statements principally which induced the author to study the action of heat upon various liquids under different degrees of atmospheric pressure and other alterable circumstances. Everyone is acquainted with the fact of water boiling quietly in an open saucepan, whilst the same liquid behaves very differently when heated in a long glass tube drawn out to a fine point, which, permitting the escape of the steam, would not allow the water again to absorb the gases of the atmosphere. Under these circum-

stances the "bumping" or convulsive ebullition which is also to be noticed in the distillation of sulphuric acid, was observed; and if further the air-pump were employed to facilitate the extraction of the air from the water it might happen that the application of heat would induce a sudden and violent escape of vapour amounting almost to an explosion. Another illustration of this fact could be seen by placing a flask with a little hot water under the receiver of an air-pump and then arranging in connection with the same a platinum wire which could be heated to a tolerably constant temperature beneath the surface of the water, by means of a galvanic battery. On exhausting the air it would be found that the ebullition only occurred at intervals, often a minute would elapse and then a burst of vapour would almost eject the contents of the flask. This over, the water would again become perfectly tranquil and remain so for another minute, when another tumultuous ebullition would occur, to be succeeded by a period of rest; and the same phenomenon would be repeated at such regular intervals that the apparatus might almost serve as an indicator of time. If a thermometer were placed in the flask it would be found that the temperature alternately rose and fell some few degrees. Indeed it could not be asserted that the boiling point of water was constant, for it depended upon the amount of air in solution, and the author believed that no one had yet succeeded in observing the boiling point of absolutely pure water. As a proof of the difficulty experienced in entirely expelling the air (or dissolved gas) from water, Mr. Grove cites the following experiment:—A long glass tube closed at one extremity was bent in the middle nearly to a right angle; the closed limb was then half filled with water, from which, by long boiling, the air was supposed to have been expelled; the remaining space in the tube was then completely filled with olive oil, and the open extremity was dipped into a small basin of the same. Heat was now applied to the tube until the water boiled, and this temperature was maintained for a considerable time. Each bubble of steam which left the surface of the water passed through the column of oil, becoming smaller and smaller during its ascent, but never did it condense without leaving a microscopic bubble of gas, which at length accumulated to such an extent that it could be examined. It was found to consist of pure nitrogen. The author had never succeeded in expelling the whole of this gas from aqueous solution even upon evaporating the entire bulk of the water itself; the evaporation of nineteen-twentieths did not secure the immunity from nitrogen of the remainder. On boiling ordinary water, air containing a slight increased proportion of oxygen was first driven off, the oxygen gradually diminishing until pure nitrogen was expelled. The avidity with which such water again absorbs air is remarkable. In the expressive words of Mr. Grove, "it sucks it up again almost as a sponge takes up water." By a slight modification in the apparatus the experiment was repeated with mercury instead of oil, in contact with the boiling water. It furnished a similar result. Mr. Grove next took bromine in order to test the possibility of converting into vapour an absolutely pure liquid. This elementary substance was boiled for a long time in a long glass tube, the extremity of the tube was sealed at the blowpipe and the contents afterwards examined. It was discovered in this instance that a certain amount of pure oxygen occupied the space above the liquid bromine. The liquid chloride of iodine behaved in a precisely similar manner. Even sulphur and phosphorus when strongly heated in a closed tube over mercury gave off in each instance a gas which proved to be either sulphuretted hydrogen or the non-inflammable modification of phosphoretted hydrogen.

With respect to the decomposition of water by heat, Mr. Grove described several experiments which indicated clearly the power of a heated platinum surface to effect the disunion of the gaseous components of aqueous vapour. Water was kept boiling in a long upright tube, the closed upper extremity of which had a loop of thin platinum wire

sealed within the glass: by connecting this wire with a battery, and passing an electric current sufficient to heat it to redness, it was found, by condensing the steam, that a small bubble of oxyhydrogen gas, mixed with a little nitrogen, remained. The volume of explosive gas did not, however, increase, for a state of equilibrium was soon arrived at, when the degree of dilution by steam was sufficient to counteract the tendency to recombination, but the author had, by a different arrangement, succeeded in augmenting this effect. For this purpose he used a glass bulb for the insertion of the platinum wires, and the steam partly decomposed escaped through a constricted passage into another tube or limb of the apparatus, where it was altogether out of the influence of the heat which would have caused its explosion. For the more rapid decomposition of water, an apparatus was devised in which steam, being disengaged from a silver generator, was passed through a short tube of platinum, intensely heated by means of a blow-pipe flame; the mixed gases resulting were swept out of the apparatus as soon as produced, and might be collected in notable quantity.

A number of striking facts regarding the solubility of gas in water were finally enumerated. The general conclusion drawn from the foregoing experiments being to the effect that water had a very powerful affinity for the gases of the atmosphere; that by several processes the oxygen could be eliminated, but the nitrogen resisted all attempts to expel it from solution; so much so that it might be doubted whether chemically pure water (*i. e.*, a compound of the two elements oxygen and hydrogen only), had ever been prepared; and further, that ebullition (as applied to water), under all circumstances, consisted merely in the production and disengagement of bubbles of aqueous vapour formed upon a nucleus of permanent gas. The question, therefore, was raised as to whether nitrogen is so absolutely inert a body as had formerly been supposed? Many facts seemed to show that there was some hitherto undetected relation subsisting between nitrogen and water, for they were always associated together in nature, and once combined, their disunion appeared impossible.

THE IRON PRINTING PROCESS.

A CORRESPONDENT of the *American Journal of Photography* describes another modification of the Iron Printing Process. We do not remember that oxalic acid has been used in clearing the whites; in other respects the process does not appear so useful as that which Mr. Reynolds described a year and a half ago. The correspondent above referred to writes as follows:—

"The 'blue process,' of which I send some specimens, presents very soft pictures, free from all the sharp or harsh effects which the same negatives would produce in ordinary printing. For this charming novelty in our art, we are indebted to Mr. Matthew Carey Lea, of this city, a gentleman of fortune, leisure, and high scientific attainments. He does not lay claim to the discovery of the sensibility of peroxalate of iron to the action of light, being aware that Herschel long since proposed its use for photographic purposes, and that, like many other important matters, it has been lost sight of from time to time, and periodically *re-discovered*. The usual course has been to develop simply with ferridcyanide of potassium. This always affected the whites to a very considerable extent, and rendered a *previous washing* necessary, which greatly injured the force of the proof without more than partially protecting the whites.

"As the whites contained unreduced persalt, it seemed probable that their discoloration was in some way caused by the production of prussian blue, whereas the picture proper was composed of Turnbull's blue, $3 \text{FeCy}_2, \text{Fe}_2 \text{Cy}_3 + x \text{HO}$. Recollecting that the former of these blues was soluble in oxalic acid, and the latter not or less so, it occurred to Mr. Lea that that acid might be available for obviating the difficulty. Experimenting proved this to be the case. The

preliminary washing was dispensed with, the excessive over-printing previously required became unnecessary, and the print was developed with a force and beauty, and a perfect clearness of the whites, of which the process was previously ineapable. It became the subject of many experiments to decide whether it was most advantageous to introduce the oxalic acid before, with, or after the developer; and from his trials he has adopted the conclusion that, in over-printed proofs the first is the best, in rightly timed prints the second, and in cases of over-exposure the third. In this employment of the oxalic acid to clear the impression, to un-blue the whites, and thus soften the shading as well as preserve the lights, Mr. Lea is believed to be the originator or inventor: without his improvement such a process could never be satisfactorily employed.

"The process as now laid down is simple, and as sure as it is simple:—

"Process.—Float the paper for a very short time (say a minute at most), on a solution of the double salt peroxalate of iron and of ammonia. Dry it thoroughly in the dark. Then expose under a negative for a short time (which will, of course, vary according to intensity, season, &c., but need never exceed three minutes in the sun); on re-entering the dark room, no impression is visible upon the paper, but the print will start up (about as quickly as a collodion picture under iron development), when immersed in a developer of—

Saturated solution oxalic acid	4 parts
Red prussiate of potash (ferrideyanide)...	1 part
Water	25 or 30 parts.

The print very soon reaches its maximum, and requires but little after washing.

"In consequence of the great sensibility to light, the exposure is so brief that printing can readily be done in rainy and dark weather. It works perfectly in the enlarging camera. The printing and development are so easily and promptly accomplished, that many galleries will probably adopt the process for exhibiting a proof to a customer as soon as the negative has dried.

"I have been agreeably surprised in finding that the sensitized paper has kept well (in the dark) for forty-eight hours. I use the same developer in a dish for a number of prints. The oxalate bath must be carefully preserved from the light; I coat my bottle with black paper.

"The double oxalate is prepared by either dissolving hydrated peroxide of iron to saturation in binoxalate of ammonia; or else by dissolving peroxalate of iron in neutral oxalate of ammonia."

ART IN PHOTOGRAPHY.

BY M. BLANQUART EVRAUD.

PRACTICAL METHODS.—MANIPULATIONS.

1. *Action of Light.*—It was our desire to delay the publication of this article, in order to perfect our means of execution, but the approach of the photographic campaign, and a wish to escape the reproach that might be laid against us of insufficient information, if the results that must follow the application of our theory are not obtained, does not permit of our delaying longer.

We have stated that it was possible to continue, out of the camera, the action of light upon the image formed, so as to give to this image more intensity.

We conceive that, from the possibility of lighting the whole, there results that of lighting certain parts only, at pleasure, by screening from the action of light those parts which we desire to preserve in their primitive state.

How to obtain this result is what we now proceed to describe. But we hasten to say that we have no intention of giving artistic instruction in this place. Art will not proceed from chemical manipulations and reactions; art is

the selection of effects. We shall point out how to obtain them, not where they must be produced.

Sacrificing certain parts of a subject to bring out others with more powerful effect, with only ordinary lighting, as in a magic picture by Rembrandt, or to demand from nature a vivid and piquant lighting, as in the Spanish school,—the photographer can in future arrive at both of these results with the same material appliances.

Let us, in the first instance, state that we give a certain preference to one kind of negative over another. Thus, pictures of medium intensity, rather weak than strong, are those with which we are best satisfied, and for this reason. Their deficient intensity causes them to be rejected in practice, because in printing they yield dark positives without brilliancy in the lights, but this condition is very favourable. All the parts which we desire to retain in a state of comparative obscurity we require to be in the primitive state of the negative; that is, we protect these parts from the action of light while we submit the others to it.

To make these reserves is a very simple matter, with a miniature-painter's brush filled with opaque pigment ground in oil or in varnish, we draw as accurately as possible on the back of the negative (which is not covered with collodion) the outline of the parts which we wish to protect from the light. When this line is well defined, which, as the negative is transparent is extremely easy, we cover those parts with opaque pigment.

In this state we expose the painted side of the negative to the sun.

The luminous rays traversing the parts not covered by paint, it is upon these only that their colouring action is exercised.

It may be conceived that in this manner we may perfectly succeed in defining the parts we wish to be acted upon and those we wish to reserve.

Sufficient sharpness is obtained almost without any precaution. Besides, there will be as absolute a sharpness as can be obtained by the point of the graving tool, if we expose the negative upon a movable frame, moving it according to the meridian and the height of the sun above the horizon, so that the rays may always traverse the negative perpendicularly through the thickness of the plate.

The mass of great lights being obtained, the operation of the reserves may be continued at will; we then cover with pigment all those parts considered sufficiently lighted to expose anew to the light only those which require to receive a more intense action.

It may be seen that we can thus vary to infinity the luminous effects, as we can graduate at discretion the luminous intensities.

When it is supposed that the desired effects are obtained, the pigment on the back of the negative is removed: it requires only ordinary talent to appreciate the value of the lights produced.

It is scarcely necessary to say that, if the desired effect is not completely attained, it is only necessary to re-expose to the light the parts which require to be more strongly impressed; here our task is similar to that of the engraver, who "touches up" his plate until he obtains the desired effect.

Of Dis-Iodizing.—The action of the light (exposure) being terminated, in proceeding to dis-iodizing, we have at our disposal two methods to follow, according to circumstances or choice.

If the negative be strongly coloured, and with the intensity necessary to yield brilliant positives in printing, it is sufficient, in order to dis-iodize it, to introduce it into a bath of hyposulphite of soda. We watch the action of the re-agent which, in dissolving the iodide, causes the pearly hue of the collodion film to disappear, and renders it quite clear and transparent.

If, on the contrary, for want of time, or from not having at our disposal rays of the sun strong enough to act with great energy, we conclude that the negative has too little

intensity, it must be submitted to the action of chloride of gold, according to the valuable method indicated by M. Fizeau for daguerreotype plates.

We will briefly describe this method for the benefit of those among our readers who have not practised daguerreotype. Upon a plate carefully levelled upon a stand pour a solution of *sel d'or*, as thick as possible; the picture thus covered, the plate is warmed over a spirit lamp. Under the action of heat the gold is precipitated, and the picture changes colour. In the present case we replace the daguerrian metal plate by our negative on glass, which we submit to the same kind of treatment: from a grey or red hue the picture acquires a deep black hue, viewed as a transparency, and bronze green when viewed by reflected light.

Opacity will naturally result from the quantity of gold precipitated; therefore we heat it strongly to obtain an abundant precipitate, and employ a very strong solution of gold (one part gold to one hundred parts of water).

This process, as may be seen, is of itself an excellent mode of strengthening, for, far from fogging the shades and thickening the lights, as but too frequently happens in repeating the silver solution, it gives great firmness to the lights, without impairing their limpidity; and in place of fogging the shades it clears them, so to speak, by a commencement of solution of the iodide of silver in the collodion.

But in the special case that now occupies us, it has a more precious value than if it acted only as a simple strengthening—it is that of producing a much more energetic action on the points acted upon anew by the light, than upon those which have been protected; in our practice we are also almost always tempted to submit all our negatives to chloride of gold, before proceeding to dis-iodizing.

After the chloride of gold has cooled, the excess is collected to serve again, after the addition to it of more chloride, in order to maintain the strength of the solution; the negative is afterwards submitted to the action of hyposulphite of soda to be dis-iodized, then washed in abundance of water and dried.

Of the Shades.—It has been remarked that when we have to treat a thin negative, such as certain reducing agents, and especially acid sulphate of iron yield, we can utilize as shaded parts, for the general effect of the picture, those parts of the negative which we have withdrawn from the new action of light. By these simple means it may happen that we obtain sufficient shade. If however, we do not, and it becomes necessary for the effect, to sacrifice certain parts still more, the following is the method to be employed to obtain this result.

Upon a piece of paper placed upon the back of the negative, trace the outlines of the parts to be put into shade, cut out this outline in thick paper or cardboard, so that when this cardboard is applied to the proof, the open parts leave exposed the spaces upon which we must operate, and that the full parts cover the spaces to be reserved.

Then prepare a dish which is placed upon a truly horizontal plane, spread upon it a coating of iodine, and place the negative covered with its card screen upon the dish; the fumes of the iodine go to the parts of the image remaining uncovered, and form with the metal an iodide of silver. The coating is thick in proportion to the length of the exposure.

The iodide of silver being soluble in hyposulphite and its analogous salts, it is sufficient to pass the negative rapidly through it to dissolve all the iodide formed.

By these means we may carry the shades to any depth we choose, as we can, if desired, convert all the metal into iodide.

The degree at which the iodizing must be stopped cannot be taught; experience only can show it, but the operator may easily arrive at judging of it by the colour the proof assumes.

We may comprehend also, that it is always prudent to keep below the effect, as we can always recommence the operation; the negative, dis-iodized, washed and dried, may

be submitted to the action of iodine, until the picture is completely absorbed.

We will conclude by a remark that is not without importance; it is, that the iodizing presents less danger when the negative has been passed through chloride of gold as indicated above. The layer of gold covering the silver checks the action of the iodine, and thus permits of conducting it more surely to the point at which it is useful to stop it.—*Le Moniteur de la Photographie.*

PREPARATIONS EMPLOYED IN THE COLLODION PROCESS FOR POSITIVES.

BY CHARLES WALDACK.*

DEVELOPER FOR POSITIVES.

THE substances used in the developing solution are as follows:—Sulphate of the protoxide of iron; acetic acid; alcohol; water; nitric acid; nitrate of potassa; nitrate of silver.

SULPHATE OF IRON.—Recrystallised sulphate of iron is sufficiently pure. This salt has to be put in a well-stoppered bottle to prevent its becoming yellow on the surface, and efflorescing.

ACETIC ACID.—Either glacial or common acetic acid may be used. The latter is generally three times as weak as the former. Acetic acid must be free from sulphuric, sulphurous, and hydrochloric acid, as well as from all tarry impurities. Commercial acetic acid of the best quality is in general sufficiently pure.

ALCOHOL.—Ordinary alcohol may be employed.

WATER.—Either rain or distilled water may be used.

NITRIC ACID.—Nitric acid must not contain any hydrochloric acid. It is preferable to use nitric acid chemically pure.

NITRATE OF POTASSA OR SALTPETRE.—The nitrate of potassa must have been refined. That which is used for the manufacture of gunpowder is the best. The impurity most to be feared is chloride of potassium, which, if it were present, would precipitate the silver in the state of chloride.

NITRATE OF SILVER.—The nitrate of silver of the bath is generally used.

Collodion positives may be divided into two classes: one in which the whites are dead; the other possessing brilliant and more or less metallic whites. These two classes of prints are obtained by two different developers. Thus the positives with dead whites are developed with a solution containing much iron, and, consequently, more rapidly. The brilliant positives, on the contrary, are developed with a weak solution, rendered still less active by the addition of nitric acid.

The following are the formulæ for the two solutions in question:

FOR DEAD WHITES.

Sulphate of iron	3 drachms
Water	6½ ounces
Acetic acid (commercial) ...	4 drachms
Alcohol	3 "
Nitrate of potassa	30 grains.

FOR BRILLIANT AND METALLIC WHITES.

Sulphate of iron	2½ drachms
Water	12½ ounces
Commercial acetic acid ...	2 drachms
Alcohol	3 "
Nitrate of potassa	1 drachm
Solution of nitrate of silver ...	1 "
Nitric acid	20 drops.

In those formulæ the salts are pulverized and dissolved in the water, after which the other ingredients are added. Care must be taken not to add nitric acid directly to the sulphate of iron in a solid state, because the latter would be oxidised and transformed into the sulphate of the sesquioxide, which is not a developer.

* *Humphrey's Journal.*

The effect of nitric and acetic acid is to preserve the blacks and to render the whites more brilliant. Both nitrate of potassa and nitrate of silver produce also the same effect. Alcohol is added to cause the solution to flow easily over the plate without separating from the surface and without producing grease marks.

The preceding formulae have been verified by practice. We do not pretend to give an explanation of the peculiar effect of each of the substances contained therein. Why, for instance, are acetic and nitric acids used in the same preparation, since they are supposed to produce the same effect? It is possible that the second formula which is here given, might be simplified, but we prefer giving it such as it is, for we have always had good results from it. This is the one which we specially recommend.

The editor of *Humphrey's Journal* adds, on publishing this article: "It works magnificently, and especially with a white background, producing an effect of roundness more like that of a daguerreotype."

SCIENTIFIC PHOTOGRAPHY.

BY M. ERNEST LACAN.

THE human jaw-bone that has recently been found in the *diluvium* near Abbeville, a geological stratum in which no similar vestige has hitherto been discovered, has been photographed by M. Potteau, of the Museum of Natural History, to whom we are already indebted for an interesting collection of the various races of mankind.

We have before us two proofs representing the two sides of this curious *débris* of a generation, the existence of which, in all probability, refers to the pre-historic period. It is the half only of the lower maxillary bone, in a truly extraordinary state of preservation.

From observations which have been made, and which we owe to the kindness of M. de Quatrefages, this jaw belonged to an old man of short stature, which tends to prove that the human race had not, at its origin, those gigantic proportions which certain hypotheses have assigned to it. The angle of the external contour is more open than in the modern types, but upon examining two Esquimaux jaws we saw that in one this angle was still more open, and in another much less. This is, therefore, a characteristic belonging to the individual. A molar tooth remaining in its place, appears also more inclined forward than in ordinary cases; but this fact is explained by the absence of the adjoining tooth, which had been extracted or had fallen out during life-time (for the work of ossification had taken place, as usual, in the alveolar process). This, therefore, is nothing but an individual peculiarity.

Other less important observations, which may be repeated on the photographic proof itself, give the same result.

The discovery of this fossil jaw has caused a true scientific tourney between the French and English *savans*. If victory remains with the first, their adversaries have possessed the rare merit in duels of this kind, of frankly and courteously acknowledging their defeat.

To give some idea of the minuteness of the investigations entered upon, so as to remove any doubt that might exist, we give a summary of some of the curious details with which we have been kindly furnished by MM. de Quatrefages and Milne Edwards, fils.

After examining the jaw found by M. Boucher de Perthes, M. de Quatrefages repaired to the mill at Quignon, where the excavations were made, to study the ground. He examined the place where the jaw had been found, and struck a pickaxe into a spot at about the same height from the ground. A quantity of flints were removed and among those that fell he found an axe-head of flint, similar to those of which we already possess numerous specimens. Upon examining the spot which had been attacked, M. de Quatrefages found almost entirely embedded in the soil a second axe-head, which he removed himself. This latter, at least,

could not have been fraudulently introduced, and its presence was a guarantee of the authenticity of the human *débris* found in the same place. Upon this the learned Professor made his first communication to the Academy of Sciences. Mr. Falconer hastened to Paris, examined the jaw-bone and axe-heads, and appeared convinced. However, after a few days spent in further observations, he published in the *Times* a letter which expressed more than a doubt. M. de Quatrefages thereupon resumed his examinations, and replied to the criticisms of his friends across the Channel. The latter then decided that they would proceed to Paris to witness, in company with certain persons they should designate, the investigations of which M. Milne Edwards had spoken in his communication to the Committee of Learned Societies.

Three principal points served as the base to the doubts of the English professors; viz., the nature of the envelope of the jaw-bone and axe-heads, the freshness of the edges of the latter, and, lastly, the presence of a little sand in that part of the jaw-bone through which passed the dental artery. M. Delesse declared that it would be impossible for any chemist to counterfeit the substance of which the envelope was composed. Five axe-heads were successively found in the presence of the persons making the inquiry, and they each and all had the same characteristics as those previously dug up. Lastly, over the black stratum, where the maxillary bone rested, a sand was found exactly similar to that observed in the alveolar process of the jaw-bone.

After these proofs, the English *savans* declared themselves convinced that the jaw-bone had not been fraudulently introduced into the stratum of diluvium, and that it was contemporary with the materials composing that stratum.

As to the question of ascertaining the date of the formation of the soil, it remains to be solved, for M. Elie de Beaumont denies that this soil really belongs to the diluvium. Such is the position in which this interesting debate stands.—*Moniteur Universel*.

ABOUT COLLODION, ETC.

BY J. MILTON SANDERS, LL.D.*

SUCH a vast amount of literature, good, bad, and indifferent, has been written upon the subject of collodion, that to attempt an article upon it this late day, seems really live folly. But something can be said that may be valuable, upon the most trite and threadbare subject, provided that it is built upon indicative experiment. Like hundreds of your photographic brethren, we, too, have made many experiments upon collodion.

The whole tribe of iodides and bromides have been enlisted in our service, not to mention likewise the fluorides and chlorides. As for the proportions in which we have combined them, the mere enumeration would be equivalent to burthening an entire column of the photographic journal with meaningless formulæ.

In order that you should get good collodion, it is quite necessary that all of the materials should be perfectly pure. This has been so frequently mentioned by others, that it would appear superfluous here; but to bring it to the meditation of the reader, is again necessary. It would be invidious to dwell particularly upon the cotton and chemicals of any particular manufacturer, but while we mention that we use none but those prepared by Seely and Co., we would not by this depreciate those of other chemists. The iodides and bromides should be mixed in the proportion of the equivalent number of their radicals. We find that these proportions give much more satisfactory results than in other proportion. The film yielded by them possesses the property of great tenderness, creaminess, and sensitiveness, while the collodion resists the action of time better than any other I have ever yet used. The manner of preparing this collodion

* *American Journal of Photography*.

is as follows:— Into a bottle of a full pint capacity, I pour eight ounces of pure ether; then add to it eighty grains of gun-cotton. After the cotton has become thoroughly saturated with the ether, I then add eight ounces of pure photographic alcohol, when a slight agitation will cause the cotton to dissolve. I then add eighty grains of iodide of cadmium, and sixty grains of the bromide of the same metal; shake and they will soon dissolve, and the collodion is made. The above proportion is nearly in round numbers those of the equivalents of the radicals used.

It has been asserted by some writers, that bromine had a tendency to render the film less dense and less sensitive. I find, after having made hundreds of experiments, that the reverse is the case. The sensitiveness of the film so highly bromized, is considerably increased, and the toughness likewise. The most delicate half-shades are yielded by this film, either in negatives or positives.

We would mention in conclusion, that we never acidify a bath with acetic acid. Nitric acid, the one that silver is combined with, it is that we use. It is the acid that should be used for the purpose of acidifying the bath, provided an acid be necessary at all, for we find that the majority of nitrate of silver is just acid enough to answer the purpose of a bath without the addition of any acid whatever. If known, it should become necessary to acidify the bath, use nitric acid and you will avoid much trouble. When we were in the habit of using acetic acid in our bath, we were frequently in trouble, the plate presenting those familiar aspects so well known to the photographer, such as spots, streaks, mottlings, thin translucent films, &c. All of these may be avoided by using exclusively nitric acid.

Some have asserted that this acid yields films less intense than acetic acid, but we have not found this to be the case; while there is one advantage, that whiter and finer ambrotypes are the result.

And finally, we would conclude this article by mentioning that, like perhaps many other photographers, we have entirely discarded alcohol from our developer. The alcohol, many photographers inform us, is necessary to assist the fluid to flow evenly over the plate. We find no difficulty in flowing the non-alcoholic developer over the largest plates, then wherefore the necessity of alcohol? When there is no necessity of an article, wherefore its use? By the non-use of alcohol we avoid many disagreeable marks upon the film that once troubled us.

This is the place where we had intended to bring this paper to a close, but a few words more on the cleansing of the bath. It was the discovery of Professor Seely, and was first announced by him, that the direct rays of the sun did not actually ruin the bath, as was then universally believed, but on the contrary, they purified it. As soon as our bath begins to exhibit symptoms of "general debility," as the doctor would write it, we pour into a shallow, open basin, and set it in the sunshine. The organic matter, together with a small portion of silver, will be precipitated, while at the same time the alcohol that the bath contains will evaporate. It would perhaps be well to mention that, before the exposure of the bath, the acid in it should be neutralized, as organic matter is soluble in acids.

The bath should be then exposed for about one hour, when it should be filtered, slightly acidified with nitric acid, and our word for it you will find it to work, with the above collodion, like a charm. If it does not, you may consider your bath so far beyond "general debility" as to be at the point of death. The best way, in the latter case, would be for you to precipitate your silver as the carbonate, dissolve this in nitric acid and make a new bath.

In the above, we yield to the imputation that we have written some things which are old; but you should recollect that all old things are not unworthy of attention, even in this age when new things appear to be the rage, whether they possess merit or not.

IMPURITIES IN ALCOHOL.

THE question whether the use of methylated spirits in collodion is really injurious, is not decided. We are of opinion that conclusions as to its injurious operation have been too hastily arrived at. It may be, however, interesting to possess a certain method of detecting the presence of wood spirit by certain tests, although the sense of smell will readily detect it when present in any serious amount. Mr. E. J. Reynolds, in a paper recently read before the Royal Dublin Society, proposes the following method of detecting the presence of any trace of the wood spirit.

A small quantity of the suspected liquid is distilled, and to the distillate a little dilute solution of chloride of mercury (corrosive sublimate) is added, and finally excess of caustic potash. The whole is then warmed, and, if it be found that the oxide of mercury first thrown down is not redissolved, wood spirit is not present. If the excess of potash and subsequent heating of the liquid causes the re-solution of the oxide, it is divided into two parts. To one *acetic acid* is added cautiously this causes the formation of a yellowish bulky precipitate after a short time. The remaining portion is boiled strongly, and a similar precipitate is thrown down; thus proving with certainty that wood spirit is present. In applying this test, it is necessary to be careful not to add too much of the mercurial solution, otherwise an insoluble compound would be formed, and, as a consequence, a negative result arrived at. It seems this reaction is due to *acetone*, an invariable constituent of wood spirit.

The following on other falsifications of alcohol is from *L'Invention*.

Alcohol, as we all know, is the product of the distillation of sweet liquors; we draw it by the distillation of wine, of cyder, of beer, and all liquids which have undergone aleoholic fermentation. The wines which are gathered in France are not all destined to be consumed in nature. A part of the wines of the Meridian, from raisins (meaning grapes) rich in sugar, are converted into alcohol by distillation. We choose generally the white wines, which do not contain more alcohol than the red wines, but which furnish one more fine and straight in taste; the alcohol which comes from the fermentation of raisins is ordinarily impure. It contains an essential oil which gives it in some cases an agreeable savour, in others a taste disagreeable. One can at least detect the presence of this oil in the alcohol of wine not rectified. In spreading the liquor with six parts of water and distilling it with precaution, it remains in the *cornue*, an oily layer. This oil is very abundant in the brandies which come out of the *marc* of the vintage; it is produced principally by the pellicles of the grain; one hundred litres of alcohol, separated, contains twenty grammes of this oily matter formed of the oil of the potato, of oily fat; of which a single drop suffices to infect one hundred litres of brandy. One can separate this oil of alcohol by a distilling pipe with management; in fact, the alcohol drinks at about eighty degrees, and the oil in question does not enter into ebullition but between one hundred and thirty and two hundred degrees. The wines of the Dauphin and of the Vivarais of the Moselle give the alcohol which participates of the taste of *terroir*, that characterizes these wines.

It is, probably, to circumstances of this nature to which we must attribute the taste and *bouquet* in the old *eau-de-vie de cogniac*. During a long time brandy has been obtained through distillation by a naked pipe; unless one operates on white wine of a good quality, it is rare that we obtain an alcohol exempt from the taste of *marc*, or fire, contracted through this mode of distillation. The idea of substituting another mode for the one just mentioned belongs to Argand, the inventor of the lamp with a double current of air, *de quinquet*. The processes of Argand were perfected by Edward Adams, who operated with an apparatus of De Wolf's, in which the flasks filled with wine were heated by steam. One concedes that with this system, each flask, when unequally heated, gives an alcohol of different degrees. The processes of Adams were notably perfected by M. Blumenthal, who had recourse to a continuous mode of distillation, and knew how to combine the apparatus in such a manner that even during the drainage of the wines the distillation was uninterrupted. The wine arrives upon one side, while that which preceded it comes over upon the other, after having parted with the whole alcohol which it contained. This apparatus has, since M. Blumenthal, been perfected by M. Derosne, who prevented the depuration of some of the alcohol in the draining

of the wines. This last perfection was still more simplified by M. Langier. In submitting brandies to a new rectification, one obtains alcohol of three-sixths de Montpellier; it marks thirty-three degrees by the alcometer. The alcohol is received in vats, in which a part of the colouring matter is dissolved; this colouration becomes apparent as the sojourn of these liquids in barrels is prolonged. One is then disposed to allow more quality and *veluscity* to brandies which are coloured. Commerce sometimes cuts the three-sixths of Montpellier with water, and colours it with an infusion of caramel dissolved in tea, which seems to give this new brandy a taste of *veluste*, but it is rare that this falsification escapes an experienced taster.

Wine is not the only substance from which alcohol is obtained; the beet, grain, potato, certain fruits, such as chestnuts, cherries, etc., produce alcohol of a good quality, of which different kinds are consumed in brandy. Brandies are mixtures of alcohol and water, and contain about equal parts of both liquids; spirits, in commerce, is an alcohol which contains less water than brandy. The richness of a spirit is always determined by the real quantity of alcohol which it contains; it is not the same with brandy, its colour is not always proportionate to the quality of alcohol which it contains, more frequently it depends upon its age and growth. Experiments were at one time tried upon the spirits of commerce, by pouring it upon powder and then inflaming it, when the powder burned the spirit was judged to be of a strong quality; this is, however, no accurate test.

In France, the legal alcometer is that of Gay-Lussac; it expresses immediately the absolute quantity of alcohol which is contained in liquor; the experiment must be made at 15°, if the liquor has not this temperature it must be brought to it by the heat of the hand; for the rest, Gay-Lussac has given tastes of correction, which determine by the aid of the alcometer the quality of an alcoholic liquid taken at different temperatures. The principle of graduating this instrument is simple; when put into absolute or pure spirit, it is sunk to the point marked 100°, placed in pure distilled water, and it stops at the point zero, the interval between these two points is then divided into 100° by the aid of mixtures of alcohol and water in proportions which are known—this instrument indicates the relations of volume, not of weight. In commerce, Cartier's areometer or liquor-weigher is still employed; in this instrument water which is distilled marks 10°, and alcohol "anhydre," marks 44°. Brandy from wine, originally has a whitish colour, but by tarrying in open barrels it acquires by age the yellowish-brown coloration which it ordinarily has, and which is due to the dissolution of a part of tannin and the extract contained in the oak. This brandy thus coloured is blackened with a few drops of a solution of sulphate of iron. Brandy of a good quality possesses an aromatic odour, and a warm and clear savour, which is modified by time, the most esteemed brands are those of the Languedoc, of Montpellier, and the district of Armagnac.

THE STEREOGRAPH AND THE STEREOSCOPE.*

The stereograph and the stereoscope have been discussed in a scientific point of view until these subjects are exhausted; it remains now only to see whether there can be any other application of them than that which is already made of them, as well as also to show how stereographs are taken and copied.

THE APPLICATION OF THE STEREOSCOPE TO DETECT FORGERY.

If two engravings from the same plate be placed side by side and mounted as a stereograph, it is evident that, when these engravings are superimposed, either by the aid of the stereoscope or by the eyes alone, the resulting picture will be perfectly flat; whereas, if two engravings of the same object and of the same size be struck off from two separate plates, the one being a copy of the other as accurate as can be obtained by any artist whatever, or both plates pictorial representatives of the same object from the same point of view and worked by the hand, I have no hesitation in asserting that the superimposition of these will invariably produce a degree of pseudo-stereoscopia.

* Continued from p. 150, vol. vii.

Now, wherever such an irregular relief is thus produced, we may rely upon the accuracy of the deduction when we assert that the pictures are not produced by impression from the same plate. Such a deduction is the result of experiment. For instance, draw two very fine lines or arrows, each one an inch or so in length, and at the distance of two inches and a half apart; from the centre of each line, and with a radius a little greater than half the line, draw a circle; let these two circles finally be so arranged on a stereoscopic slide as to revolve round their centres respectively. So arranged place the slide in the stereoscope, and revolve the circles until the superimposed lines lie on the same plane with the circles; when this is accomplished, and it can be easily and very accurately accomplished, it will be found that the arrows are in exact parallelism with each other. The *slightest* deviation from this parallel position will elevate one end of the arrow and depress the other, so that it appears to be inclined to the surface of the circle. The perception of this phenomenon is very easy; therefore, the slightest irregularity in the position of the corresponding parts of two drawings so treated becomes manifest by producing relief where, if the corresponding parts were all accurately at the same distance apart, such relief could not exist.

Taking advantage of this peculiar property, means can be adopted to detect forgery, that is, to distinguish very easily and quite undeniably, a forged bill from a true one.

In order to apply this property to the bills of banks, where fraud is suspected, we proceed as follows:—Take a true bill of the bank and the suspected one, double them in the middle carefully, and place the similar halves of either on a stereoscopic slide side by side like the two photographs on such slides; make the surfaces as smooth as possible, and bring the corresponding lines of either to coincide so as to form, as it were, one and the same straight line. If these two bills have been struck off from the same plate, the superimposed picture will be flat; if, on the contrary, they are the impressions of two separate and distinct plates, one being a copy of the other, an irregularity of relief in the position of the words when superimposed will indicate the fact that one is either a copy or a forgery.

A second method of detecting forgery refers to photographic copies of bills, which, when superimposed with the original bills as above described, may produce a flat picture in the stereoscope. In this case the forgery is made apparent by the difference in the gloss of the written signatures or, where this fails, then a chemical experiment or two performed upon a minute point of the writing will set all doubt aside as to whether forgery has been committed or not.

Correspondence.

PHOTOGRAPHY IN NEW YORK.

New York, June, 4th, 1863.

DEAR SIR,—My statement that our great American globe lens was not up to the popular idea, has raised a dust around my head here, and has brought out a letter from the manufacturer, in which he says:—"We never claimed for the lens an angle of 100°, nor do I think it has been so stated in any publication except the English journals, and then ironically. The true angle is 75° or 80°, i.e., the lens will show a well-defined and equally illuminated circular field, including that portion of the horizon." The 75° I admit, and even 80° is included in this lens; which certainly covers a wider field than any lens yet sold,* but we were

* Our correspondent is here speaking in the absence of personal knowledge of the triple lens. The angle included by the globe lens is probably about 75° measured on the diameter of the circle of light. It is customary, however, to measure the angle on the horizontal line of the picture which can be cut from the circle. Such a step would probably reduce the angle included by the globe lens to about 60°. We have now before us an interior taken with the stereoscopic globe lens in which it has done its work well; we have also a view of the same interior taken with Dallmeyer's No. 1 triple, in which the work is also done well. But the square cut out of the circle given by

given to understand that the globe would take in 90°, which I think was not so. I know nothing of optics and, therefore, may be wrong when I say my idea of 90° is to set the lens thirty-seven and a half feet from the ground at a distance of thirty-seven and a half feet from a building seventy-five feet high and take in the whole height without curved lines or other distortion. The Harrison lens, however, certainly *does* do 75°, and does it well. This statement is due to the manufacturer, and I freely make it.

Photographically speaking, we have a dearth of news on this side the ocean, although the business of galleries and stock-dealers never was more brisk. I enclose *The Print* from which you will see that the amateurs are lively as ever. Mr. Guillou, of Philadelphia, has sent me some *blue photographs* which are quite curious and very beautiful. For some subjects this process (published in *The Print*) may be desirable, but it never can be used in any portraiture.

Some interest is excited here by H. T. Anthony's oxide of silver process. I have made some prints by it with great success, and am determined to adopt it in future practice. At the next Club Exchange I intend exchanging prints made with only fifteen grains of silver to the ounce of water.

Process.

Nitrate of ammonia	3 ounces
Filtered water	10 "

Shake up and thoroughly dissolve, and add moist oxide of silver to saturation. The moist oxide of silver is prepared by adding to a pint of twenty-grain solution of nitrate of silver caustic potash till all the oxide is precipitated. Wash the precipitate thoroughly to clear it of potash, and put all this wet oxide into the nitrate of ammonia solution. There will settle undissolved to the bottom of the bottle some oxide, which surplus serves to keep the bath saturated, and also to keep it clear. Add three drops of nitric acid to the ounce, and sensitize the paper by floating half a minute. After the paper is dry put it in the fuming box as usual before printing. If the albumen is soft and dissolves in floating, then add more nitric acid, and fume in the ammonia fuming box for a longer time to counteract the acid.

The extreme economy of this process is its recommendation. I will forward you some of these prints as soon as I get to rights in my "great den."—Very respectfully yours,

F. F. THOMPSON.

IRON DEVELOPER WITHOUT ACID.

DEAR SIR,—I have seen no remarks made on the formula for developing solution by M. Kaiser of Leyden (see PHOTOGRAPHIC NEWS, May 29th); its importance has seemed to me to make it worthy of investigation and trial, and from the perfect success of my first essay in development with iron without acid, I am convinced that it needs but to be made known again to be fully tried.

I employed honey in place of sugar of milk, as directed by M. Kaiser, and if any one will just perform the experiment of dissolving about equal parts of honey and water together (or make a strong solution of honey), containing a few grains (10 or 12 or so), of sulphate of iron per ounce, adding *no acid*, and mixing with it some nitrate silver solution, as in developing, he will at once perceive the great lapse of time before the decomposition of the nitrate silver will set in, far longer than with acid and iron developer. I next sensitized a plate, exposed, and developed it into a clear, vigorous and dense picture, using a like developer viz., sulphate iron, honey, and water; it may be an accelerator as M. Kaiser says, no acid being present, and it is so anomalous, after the hitherto received belief of acids being a

the globe lens includes less subject by several degrees than the square cut from the circle given by the triple. We shall send the prints in question to our correspondent for his examination. We are not undervaluing the capabilities of the globe lens, which is an ingenious invention, and for some purposes will be found useful; but we do not regard it as equal in general utility, or in the extent of angle embraced, to the triple lens.—Ed.

sine qua non with iron salts in development.—I am, Sir, yours faithfully,
Egham, June 23rd, 1863.

WILLIAM BARTHOLOMEW.

[We have used the saccharo-sulphate of iron in very strong solution, with not more than a fourth of the usual amount of acid with advantage. It gives a denser and a browner image than the ordinary iron developer. We may here mention in answer to several who have made inquiries, that Messrs. Hopkin and Williams at our request, prepared some of the saccharo-sulphate, and are doubtless prepared to supply it.—Ed.]

Photographic Notes and Queries.

CAUTION.

DEAR SIR,—On Thursday last a shabbily dressed man applied to me for work as an artist, pitching a sad tale of distress owing to his wife being an inmate of Hanwell Lunatic Asylum, trade being bad, &c., &c., his tale somewhat exciting my sympathy, I directed him to call again with specimens of his capabilities; he paid me a visit the day following, and during my temporary absence from the waiting room he made his exit with my great coat, the loss of which I did not discover until about three hours afterwards. As near as I can remember his description he is about 5 feet 8 high, dark complexion, small black whiskers, dressed in a black coat, black or dark diagonal pattern trousers, gave the address of Mr. Campbell, 5, Church Street, Knightsbridge.* The publication of this in your well circulated NEWS may probably put others on their guard.—I am, sir, yours respectfully,
R. H. DYBALL, Photographer.
3, Lower Notting Hill Terrace, June 23, 1863.

[We may here add another caution. An artist (possibly the same man) called upon a friend of ours, a first-rate photographer, and by a variety of considerations induced him to let him have some specimens to colour, on the distinct understanding that they were simply to illustrate his abilities and not to be paid for unless approved. He also borrowed some other coloured specimens as guides as to style. When he brought back his work the photographs were spoiled, and had become miserable dabs. He however demanded payment, alleging that he had painted them to order, and on meeting with an indignant refusal, he declared that he should keep the other coloured specimens lent to him, worth several pounds, until he was paid. So the matter stands.—Ed.]

DRY PLATE TROUBLE.

SIR,—I shall esteem it a great favour if you will afford me any information which may explain the following failure:—

I prepared a plate for the dry process, as described by Mr. Hislop, using Ponting's bromo-iodized collodion, as recommended.

I kept this plate three weeks in a light, tight box, then exposed to a sunlit view (twelve o'clock) for one minute, using Dallmeyer's No. 1 triple, half-inch stop. Upon developing, not the very faintest appearance of an image was visible.

This I do not understand, for though the plate may have been under-exposed, surely *some trace* of a picture should have been found?

My bath works well for the wet process, thirty-five grains to the ounce,—very slightly acid with acetic acid.

The collodion also works well for the wet process, though it is several months old.

If you can explain this failure, I shall be extremely obliged.

Are you aware whether the tannin and honey process still gives satisfaction? and whether the plates will keep—say three weeks after exposure—before development?

I obtained some of Werge's plate-cleaning fluid, as recommended in the last number of the NEWS, and find it most efficient. It is evidently nothing but *uniodized collodion* and methylated spirit.

I had been in the habit of using old collodion and alcohol, the action of which is precisely the same, though rather more expensive. Mr. Werge may well guarantee that there is

* Upon inquiry I find there is no such place.

nothing in it which will injure the bath.—I am, Sir, yours truly,

A DRY PLATE.

London, June 23, 1863.

[Did you redip the plate in the silver bath before developing? or did you add any silver solution to the developer? Unless you made this omission—a thing we have known done—we cannot offer a suggestion as to the cause. Perhaps some of our correspondents may have had some experience in such mishaps. Regarding Werge's plate-cleaning solution, you are right as to its efficiency, but altogether wrong as to its constitution. We were entrusted, in confidence, with the formula by which it is prepared, and except that, amongst other things, it contains ether, you are in error. Tannin and honey continue in many hands to give excellent results.—Ed.]

To Correspondents.

W. H. BISHOP.—If you took the portrait for your customer without any agreement as to copyright before any of the copies were sold, you have lost the opportunity of acquiring a copyright. If you took the portrait for yourself, you might have obtained a copyright in it by registering it before any copies were sold. But so far as we understand the case now, no copyright in the portrait in question either exists or can be procured by any one. You can get any picture registered in which you have a copyright at a cost of about 1s. 4d.

AN ENTHUSIAST.—The general plan of your room is good, but we should prefer the space over head without glass to be lengthened a little, and to have the amount of glass both top and sides a little extended to meet the necessities of dull weather and bad light.

TAYLOR.—We cannot tell you to what extent the enamel paper has yet come into general use, either in London or elsewhere, and it will always involve more trouble than ordinary albumenized paper. 2. The double sulphate of iron and ammonia may be used as a developer in solutions of various strengths, the same as the ordinary sulphate. See various formulae which have recently appeared in our pages. 3. The annoyance to which you refer is a common one, and many respectable portraitists feel it seriously. You can only prevent such copying by taking steps to secure the copyright in such portraits. We shall have something more to say on the subject shortly.

A. B. D.—The salt you enclose appears to be a preparation of iron, and appears on a hasty trial to develop in a similar manner to the ordinary sulphate. To ascertain if it possess special advantages would require careful comparative trials.

A CONSTANT SUBSCRIBER.—It is a moot point whether or not a person may copy a copyright picture merely for his own private use. It is probable that a strict enforcement of the Act would punish copying for any purpose whatever.

G. A. B.—The amount of washing you describe ought to be sufficient for a tannin plate; but some samples of collodion require much more washing than others. Did the spots or mottled marks show on the plate at all before development? If so, probably the collodion is unsuitable. Possibly the development was too hastily done, and without sufficient care as to cleanliness. The plate would have been better with longer exposure. Your cards would have been better for a trifle longer exposure and less development; the definition is wonderfully good for a stereo lens of 3½ inches back focus. The stain is due to a certain condition of the bath, sometimes very troublesome in hot weather. See that there is no floating scum at the top of the solution. We have not made sufficient experiment to fix authoritatively the best strength of solution with the double sulphate. We are using it 48 grains to the ounce, with 48 minims of acetic acid, with advantage. The saccharo-sulphate may be had of Messrs. Hopkin and Williams.

TANNO-GLYCERINE.—Gallic acid is soluble in cold water to the extent of about 4 or 5 grains to the ounce. There is a slight difference in the solubility of various samples; but the use of 5 grains to the ounce will in most cases produce a saturated solution. It is much more soluble in hot water, from 100 to 130 grains being soluble in an ounce of boiling water. It may be used hot, and is then for albumen and collodion-albumen plates a very energetic developer. It is better only to heat the quantity required for use. It is very soluble in alcohol, but we cannot state the exact limit. 2. When pyroxylene has become slightly acid from age or exposure, washing it in acetate of soda, or even in alkaline solutions, whilst it may remove the acid, will not restore it to its former condition. The acid can only be liberated by decomposition, and although the acid may be removed, the former condition is not thereby restored. We have not met with the decomposition referred to; but we have found that cotton prepared with moderate care does not easily decompose when kept for many months. We have kept samples prepared by ourselves upwards of twelve months without deterioration. You are right in the estimate of the book in question. The box has just arrived, but is not unpacked. We do not remember a suitable person for the undertaking, but will give the matter our earliest attention after returning from Paris, whither we go as soon as the present number goes to press.

SOL.—Your experience is unusual. When everything is in good order a good purple tone should be obtained in ten minutes, or a quarter of an hour, although, sometimes, it is longer. We prefer slow toning; but you can generally hasten it, when desired, by increasing the strength of the solution.

W. G.—We have occasionally known similar markings to those which you describe appear on the dry plate before exposure, without affecting the negative. Its cause we are uncertain of. Sometimes it is attributed to the use of an old nitrate bath.

HONORATO.—The best place for stops in a portrait lens is between the front and back combination. As a rule, they should occupy a position governed by the respective foci of the front and back combinations. To illustrate: suppose the focus of the front combination were six inches, and of the back twelve inches, and the distance between the lenses three inches, the position of the stop should be one inch behind the front combination, which would also be two inches in front of the back combination. You

can try some stops of blackened card-board placed in the position, and see if the result is what you desire.

R. H. COURTNEY.—We are sorry we did not see you. We will give the salt a trial shortly. It appears, on a single trial, to develop very well, but to give a thin image.

TYNO.—Your bath is probably super-saturated with iodo-nitrate of silver. Add its bulk of distilled water, neutralize, sun, filter, add silver to make up the strength, and try. 2. Mr. Leake in advising the use of an acetate in the nitrate bath, and at the same time speaking of the use of carbonate of soda, is of course speaking of acetate of silver, and in adding carbonate of soda, he will either have acetic acid present in the bath, or he will add it coincidentally with the carbonate of soda, and so form acetate of silver in the bath. If the collodion to which you refer reticulate, the only remedy is mixing it with another sample.

LANKA.—The coppery-looking deposit on the deep shadows whilst developing is a familiar trouble in this country during hot weather. We wrote an article fully treating of the matter last summer, which appeared on p. 251 of our sixth volume. One of the most frequent causes for its appearance is insufficient washing between different stages of the process, especially when using some spongy samples of collodion. An excellent remedy is to flood the film before intensifying with a solution of iodine one grain, iodide of potassium two grains, in one ounce of water, then thoroughly wash again before applying the intensifier. The best remedy when this deposit has occurred is to treat the finished negative with a very weak solution of bichloride of mercury, which will, without much affecting the general character of the negative, turn the red deposit white, and so make of little account in its effect in printing. 2. Are you sure it is a fungoid growth to which you refer, or is it what is termed a "sweating" of the glass? Any form of organic matter or fungoid growth ought to disappear on treatment with strong acid, nitric or sulphuric. If you have anything suitable for publication, we do not know of any house with better facilities for distribution, or who can give you better information on the subject than Marion and Co., 23, Soho Square. 4. You can become a member of the Amateur Photographic Association. You can receive full details from Mr. Melluish, the Secretary, 12, York Place, Portman Square. We shall have pleasure in proposing you. The subscription is a guinea a year, for which members receive two guineas' worth of prints. They must contribute at least six good negatives yearly. Members receive half the profits of sales of their own prints. 5. The addition of carbonate of soda and sunning will, probably, suit your baths best. 6. Our YEAR BOOK contains an annual *résumé* of improvements in the art. Major Russell has a second edition nearly ready. There is announced for publication, shortly, a work by Bland and Co., containing full information of latest improvements; and Mr. Hughes has a new edition of his manual in the press, which will contain, we believe, very full information on many topics. 7. For certainty the collodion-albumen process; for simplicity and general advantage the tannin process, or some of its modifications.

B. B. F.—In attempting open-air portraiture you will find a blackened hollow cone, about the size of a sugar-loaf, attached to the lens, so as to project in front, will materially aid you in getting clean shadows. Your negative is evidently somewhat fogged from diffused light entering the lens.

JOHN ALEXANDER.—Your Voigtlander of 5½ inches focus will, probably, answer for instantaneous views, although its aperture is not quite so large in relation to its focus as Dallmeyer's new stereo lens, regarding which you inquire. His No. 2 B is most suitable for cards. The information you require on the manufacture of formic acid would require the whole of this page to give with efficiency.

AMATEUR.—The mottling to which you refer appears to be due to the especial lighting and extreme sharpness of the texture of the skin. A trifle longer exposure would probably have got rid of it, and would also have given more brilliancy. The chief faults in the picture are due to unsuitable background and accessories.

D.—We will mention your queries to Mr. Blanchard, as, in our experience with the formula, we have not met with the difficulties named. You may remove slight fog or excessive deposit on the shadows, by using with great care, a dilute solution of iodine and cyanide of potassium, one grain or less of each in an ounce of water. Try on a valueless negative first, as great care and quickness in washing, the moment sufficient action has taken place, are necessary.

RECENT SER.—The best strength for using the double sulphate solution depends upon many points. Try some of the formulae which have recently appeared in our columns. The salt is now to be had of all dealers, or may be made by the formula we have once or twice given, which consists in dissolving protosulphate of iron and sulphate of ammonia in their equivalent proportions in water. It may be either kept so, or re-crystallized. 2. A light grey, either of woollen cloth or in distemper colour, is best for vignette backgrounds.

THE COLLODION FILM DISSOLVING WHEN VARNISHED.

ONE of the most annoying troubles which a photographer can encounter is the loss, from any cause, of a fine negative; but his mortification is complete when the destruction is produced by the very means intended to preserve it from injury. A brilliant negative, securing some unusually graceful pose, or charming expression, in a portrait, or a choice of effect of light, with perfectly still foliage in a landscape, is fixed, washed, and dried, without a flaw. The intensity is just right, the shadows quite clean—in short, the negative is perfection. It must be varnished at once with a hard spirit varnish: the plate is warmed, the varnish poured on, when, to the horror of the operator, a transparent spot appears at the point where the varnish was poured on, and “ere a man can say behold,” the image is floating in fragments over the plate.

The misadventure is fortunately not of common occurrence, but most photographers of much experience have occasionally met with it. Dr. Wright and Dr. Diamond both mentioned, at a recent photographic meeting, the mishap as having occurred on their hands, and they both agreed in referring it to a removal of the image only, not the disintegration of the film. They regarded it as due to a peculiarly horny sample of collodion on which the image was quite superficial, not permeating the film properly. Mr. Shadbolt believed it to be due to the entire solution of the collodion film, some samples of pyroxyline being, as was well made known, soluble to some extent in strong alcohol.

Dr. Van Monckhoven, writing on the subject, stated his conviction that both opinions were partially correct. That the removal of the image was due to a partial solubility of the pyroxyline, but that a superficial layer of it only was dissolved leaving the greater portion of the film intact. He bases his conviction upon an opinion which we consider erroneous. He says:—“Many persons imagine that the image formed penetrates the film; but this is not the fact for, upon examining the film at the back of the plate, we perceive that the iodide of silver remains perfectly white. The luminous impression is confined to the surface of the sensitive film, and does not penetrate its substance.” In this view we think the worthy doctor is scarcely accurate. In some instances the image is doubtless superficial, but in others, and these the majority and the most perfect, the image is embedded in the collodion film, all, or the greater portion, of the particles of iodide, bromide, and nitrate of silver which are held in its substance when it leaves the silver bath, going to form the image. To examine by the method to which Dr. Van Monckhoven refers, we have an unfixd plate now before us in which the darkened image of reduced silver is plainly apparant by reflected light on both sides of the plate at the back nearly as plainly as at the front, embedded in a thick cream-coloured film of iodide of silver. Further, if the image were merely superficial, the subjacent layer of sensitive salts remaining

unaffected by light or development, the thickness of the film, would be altogether unimportant, and would have no effect upon the image. It is well known, however, that a collodion with a good body, giving a creamy film in the silver bath, is a most important element in securing intensity in the image. Again, if the image were entirely superficial, and the subjacent layer of collodion and silver salts were inoperative in producing the image, still less could any preliminary coating on the glass plate play any part in its formation. Yet it is well known that a preliminary coating of dilute albumen gives extraordinary vigour and warm tone to the image on plates so prepared before coating them with collodion, and rendering the conviction inevitable, not only that the image is formed right through the film, but that a substratum of a substance capable of combining with silver also aids in forming and modifying the character of the image.

Where the image is formed on the surface only of the collodion film, we regard it as a defect, which may be due to several causes. A collodion, forming a horny repellant film, especially if heavily iodized and excited in a weak silver bath, will give such an image. So completely superficial may the image be in such a case that it may be wiped clean off the collodion, whilst wet, without abrading the film or leaving a trace behind. We recently tried a sample of pyroxyline, and used the collodion, which was heavily salted, a few hours after it was mixed. The image started out vigorously, and developed, to all appearance, quite satisfactorily. But on the application of a heavy stream of water to wash the negative before fixing, portions of the image were removed in patches by the force of the water. At the expiration of a week sufficient change had taken place in the character of the pyroxyline to render it less horny, and a negative sufficiently in the film, instead of on it, was obtained by the same collodion.

We recently met with the mishap, the first time for many years, of the image being destroyed on applying the varnish; but it was manifestly the whole film which was attacked by the alcohol. It broke away and separated into fragments, some of which floated apart. Correctly speaking, the image did not dissolve: the solution took place in the deep transparent shadows, where there was no deposit of silver, and the fragments to which we refer as floating consisted of dense portions of the image formed by the silver deposit. We have one of a series of negatives upon which we then experimented, in which the hands, which were clasped resting against a dark silk dress, were dissolved from the arms, also draped in dark silk, and floated a little distance away and then stopped, giving the effect to the arms in the negative of being about half an inch longer than they were. The negatives in question were taken with an old and somewhat decomposed collodion, the cotton having originally been made at a high temperature. The varnish was made of strong spirit, and what we discovered to be the most fatal cause of all, we made the plate very hot. Having dissolved one film by accident, we proceeded with several more taken with the same collodion, for experiment.

We found it was quite possible to save the same films with care. Even with the same varnish, applied nearly cold, and then warmed just sufficiently to prevent the varnish chilling, the film was not dissolved. The use of a spirit varnish, of much more body, was also found efficient to prevent the film dissolving. It is curious, but, we believe, a fact, that when a strong alcohol holds in solution a large proportion of a gum resin, it is much less active in dissolving other substances upon which it would otherwise act energetically. The use of a varnish made with a less highly rectified spirit was also found efficient, as was also varnishes of which benzole or chloroform was the solvent.

When, therefore, a collodion has been used, the dried film of which shows any tendency to solution when varnished, there are several precautions which may be used. Besides that to which Dr. Van Monckhoven refers of applying first a weak solution of gum arabic, or what may also be used with perhaps greater advantage, dilute albumen, applied before the negative dries, the tendency may be checked by using a spirit varnish of considerable body, and made with alcohol containing a little water,* and using the least heat which will permit the varnish to set without chilling; or by using a benzole or chloroform varnish instead of one in which the solvent is alcohol.

SALE OF PHOTOGRAPHIC POISONS.

The following letter recently appeared in one of the morning papers:—

"Permit me through the medium of your journal to call public attention to the fact, that, whilst chemists generally are so restricted in the sale of poisons, vendors of photographic materials retail indiscriminately one of the most deadly, cyanide of potassium, frequently without warning of its dangerous properties or superscription of any kind on the wrapper. But for the hope that publicity may lead to the exercise of more caution in so important a matter, I would not encroach on your valuable space.—I am, Sir, yours, &c. T. J. B."

We are not aware of the recent occurrence of any mishap which gives especial force to the above letter, or directs peculiar attention to its subject at the present time. Nor, indeed, considering the familiar use of so many deadly agents as are employed in the operating room, do we think that either accidental or wilful misuse of them, to the danger or destruction of human life, has been common or frequent in the history of photography. Notwithstanding all this, however, we fear there is some good ground for the complaint in the above letter. Amongst the chemicals in use so frequent that familiarity has almost bred contempt, are several of the most dangerous and potent poisons in the materia medica. These are vended in large quantities, sometimes without label at all, and often without the warning word "Poison," which should serve as a perpetual caution as to the careless use or exposure of the fatal articles.

This is certainly not wise or desirable. We are not aware of any legislation enactment which controls or directs the mode in which the chemicals in question should be sold or labelled; but the wholesome custom of the retail chemist has established the practice of labelling with extreme care all drugs, and of adding in prominent letters the word "Poison" to all preparations dangerous to life. In regard to some especially dangerous drugs, which have frequently been used in cases of criminal poisoning, the legislation has provided distinct restrictions. A special Act was passed about a dozen years ago to regulate the sale of arsenic, the preamble of which stated that its unrestricted sale had facilitated the commission of crime. Conditions of a very stringent nature were therefore imposed as to its future sale. It was enacted that a complete record, according to a pre-

* A few drops of distilled water may be added to an ounce of varnish, with agitation. It will at first possibly turn turbid, but will clear in a few hours, or a day or two.

scribed form, should be kept in a book, of the quantity sold, the purpose for which it was purchased, the date, and the name, address, and occupation or condition in life of the purchaser. The vendor was to inquire into the truth of the statements made, and to have the signature of the purchaser appended to the entry in the book. If the purchaser were unknown to the dealer, the sale was to be executed in the presence of a witness known to both, and who should sign the entry in the book. These and some other restrictions were enacted, the neglect of any of which renders the offender liable to a penalty of twenty pounds.

Now it is obvious that such regulations, however necessary in the cases for which they are enacted, would be very irksome if extended to other not less dangerous articles; it would be wise, therefore, to avoid the neglect of reasonable precautions. If any serious accident at any time occur which shall, in any degree, be traceable to the neglect to which we refer, it might issue in legislative interference, which would go far beyond insisting on the careful labelling of each chemical with its name, and the word *poison*, wherever the article sold is of a character fatal to human life. We are not anxious to increase trouble or create unnecessary apprehension; but we think the rigid observance of the precaution we suggest is only a reasonable duty.

PHOTOGRAPHIC CHEMICALS:

THEIR MANUFACTURE, ADULTERATION, AND ANALYSIS.

MANGANESE is in many respects a valuable metal, not only to the photographer, but to all engaged in the pursuit of science; its interest being chiefly due to the peculiar affinities which it has for oxygen. The most common source of manganese is the black oxide, known also as the binoxide, or peroxide, MnO_2 . This is found native, and is known by the name of pyrolusite. In the form in which it is usually met in commerce, peroxide of manganese is an intensely black, heavy powder, prepared by grinding up the native variety. Of course it cannot be expected to be a very pure substance, and in fact it is generally found to contain iron alumina, carbonate of lime, as well as sulphate of lime and chlorides; the latter impurity is the only one of much importance, and it should be carefully removed by washing the powdered manganese with water. The chief uses of peroxide of manganese are for the preparation of oxygen and chlorine. When it is heated to dull redness a portion of its contained oxygen is evolved, and sesquioxide of manganese is left behind. If the temperature has been sufficient, between 11 and 12 per cent. of oxygen is given off. If the manganese has been free from chlorides, the oxygen is pretty pure, but otherwise the first portions of gas which come over are liable to be contaminated with chlorine. By heating binoxide of manganese with oil of vitriol, at first one-fourth of its oxygen is evolved, but at a higher heat another fourth comes off, and sulphate of protoxide of manganese is left behind. By this means more oxygen is obtained. In this process it is even more necessary to have the entire absence of chlorides than when the oxygen is prepared by the simple agency of heat, as otherwise the evolution of the whole of the chlorine in the free state is certain to take place. If the presence of chlorides be proved in the manganese, or if it be desired to remove all chance of the oxygen containing chlorine, the gas should be passed through a two-necked washing bottle, containing a strong solution of caustic potash or soda, before collection for use.

Bin oxide of manganese is also of constant use in the laboratory for the preparation of chlorine; for this purpose it is acted on by hydrochloric acid, either by the direct addition of this acid to it, or by making a mixture of common salt and bin oxide of manganese, and then heating this with oil of vitriol. In the first case the reaction is represented by the following equation.

and in the second case by

The chlorine is liable to be contaminated with free hydrochloric acid, and should therefore be washed in water, which will hold back the free acid. If required dry, it should then be passed through oil of vitriol. The commercial value of peroxide of manganese depending upon the amount of available oxygen which it possesses, several plans are adopted for ascertaining this quantity; one of the best consists in finely powdering the ore and weighing it. It is then introduced into a small flask apparatus containing sulphuric acid, and an excess of oxalic acid is added. An immediate evolution of carbonic acid is produced, owing to the union of the extra equivalent of oxygen present in the manganese, with the oxalic acid and formation of sulphate of protoxide of manganese.

From the weight of carbonic acid given off, the weight of true binoxide of manganese can be readily calculated; 44 parts of the former being equal to 43.57 parts of the latter.

There are frequently met with in nature ores containing hydrated peroxide of manganese. Of these the most noteworthy is known by the name of *wad*. This mineral is not very well defined, and most frequently contains lower oxides of manganese. *Wad* serves to prepare oxygen and chlorine equally well with pyrolusite, but not being so plentiful as the latter, is but seldom employed.

After the peroxide, the next compounds which merit attention are the acids which manganese forms by union with higher proportions of oxygen. When peroxide of manganese is ignited with caustic potash or soda in contact with air, or when fused with an alkaline chlorate or nitrate, more oxygen is absorbed by the manganese forming manganic acid, Mn O_3 , which unites with the alkali present, forming a manganate. Manganate of potash forms an intense bluish green solution, which is permanent when an excess of alkali is present. When an acid is added, or even when manganate of potash is allowed to remain in contact with the atmosphere containing carbonic acid, the manganic acid set at liberty is split up into peroxide of manganese and into another acid, permanganic acid, $\text{Mn}_2 \text{O}_7$, which instantly unites with some of the alkali forming a permanganate of an intense purple-red colour. The manganates are very little known, but by the researches of Mr. Condy the permanganates have been brought before the notice of the public for some time, and their valuable properties are now tolerably well known.

Permanganic acid in aqueous solution may be readily obtained by adding to permanganate of baryta the exact quantity of sulphuric acid necessary to precipitate all the baryta, and then filtering through asbestos or gun-cotton. Sulphate of baryta remains on the filter, and the filtrate consists of permanganic in aqueous solution. It forms a beautifully coloured liquid, which appears dark carmine red by reflected, and dark violet by transmitted, light. When somewhat dilute it is reddish blue, and a still larger addition of water gives it a carmine colour. The acid imparts a distinct red colour to very large quantities of water. It is inodorous, and has at first a sweet and afterwards a bitter, rough taste. It stains the skin brown, but does not redden litmus, as, owing to its powerful oxidizing properties, it destroys the colouring matter of the paper, at the same time turning it brown from deposition of hydrated peroxide of manganese. The aqueous solution slowly decomposes when gently heated or exposed to the light with deposition of peroxide of manganese; a dilute solution is completely decomposed when boiled, but when concentrated it may be boiled for many hours without sensible decomposition. The slight affinity which exists between the metal and the higher atoms of oxygen render this acid one of the most powerful oxidizing agents known. Hydrogen gas passed through it decomposes it rapidly with formation of water: charcoal is

rapidly attacked with production of carbonic acid; phosphorus and sulphur are raised by it to the state of acids; most metals are oxidized, and most metallic oxides are raised to a higher state of oxidation. Where possible, alcohol, ether, sugar, gum, woody fibre, paper, camphor, turpentine, vegetable oil, stearic acid, morphia, gelatine, albumen, infusion of galls, madder, and the multifarious collection of substances classed by photographers under the name of organic matter, are all burnt up by permanganic acid, and rendered inactive, generally being resolved into the ultimate products, carbonic acid and water. Other substances which would not at first sight be supposed to possess any special action upon the acid, likewise decompose it; for instance, finely divided platinum put into an aqueous solution of permanganic acid, produces a brisk disengagement of oxygen. Perhaps the most curious of the decompositions of this kind, is that which takes place between permanganic acid and binoxide of hydrogen. In this case, we mix together, perhaps, the two most powerful oxidizing agents known, and the result is very remarkable, all the excess of oxygen at once goes off with brisk effervescence, the permanganic acid being reduced to the state of brown oxide, and the binoxide of hydrogen becoming simple water.

THE PHILOSOPHY OF THE TONING PROCESS.

BY JOHN SPILLER, F.C.S.

THE chemical action exerted by the compounds of gold when employed in the process of toning photographic proofs upon paper, has engaged much attention, and been repeatedly made the subject of experiment, on the part of analytical chemists, both in this country and abroad; but, notwithstanding the numerous collection of facts already placed on record, there yet appears ample scope for diversity of opinion regarding the nature of these several reactions. In the sixth volume of this journal, at page 267, will be found a statement on this subject by Dr. Schnauss, who inclines to the opinion that the toning process is, under ordinary circumstances, the means of effecting the entire removal of the reduced silver from the print by the substitution of gold; or, at least, that this is the ultimate result when the fixing agent has fully exerted its solvent action upon the chloride of silver left at this stage on the prepared surface. Later, at page 470 of the same volume, I had the honour of communicating a series of analytical results "*On the Expenditure of Silver and Gold in Photographic Operations,*" by which I was led to believe that this interchange of metals was not usually so complete as had been represented, inasmuch as there was always a larger proportion of silver than of gold contained in the photographs examined by me; and it was further stated that even in the case of bluish-black, over-toned proofs upon albumenized paper, this was the invariable result. In consequence of my assertions, and similar expressions of opinion by Dr. Van Monckhoven and M. Girard, at the French Photographic Society, Dr. Schnauss was induced to repeat his experiments, the full particulars of which, translated from the *Moniteur de la Photographie*, again appeared (Vol. VII. p. 243) in the PHOTOGRAPHIC NEWS. On reading this second article by Dr. Schnauss it became at once apparent that the conditions of experiment were somewhat abnormal, the sensitized papers having been exposed to light until their surfaces were completely bronzed, and then, after washing, immersed for one hour in a dilute solution of chloride of gold, fixed with hyposulphite of soda, washed with dilute ammonia, and lastly with water. Plain salted paper, and another sample prepared with arrowroot, were made use of by Dr. Schnauss; and the evidence of Professor Reichard, of the University of Jena, was adduced in confirmation of the truth of these analytical results. They did not find any appreciable trace of silver on the paper toned with gold. But it may now be asked whether these conditions at all represent the manipulation generally followed by practical photographers? Is it usual to occupy

an hour in the toning process; or, even desirable, to force the print to take up the maximum quantity of gold? Provided that the desired tint of colour is ensured, it matters not how superficial be the coating of reduced gold, and it has been demonstrated by my former experiments that from two to three parts by weight of silver may remain in mechanical union with one part of gold with very satisfactory results as regards the colour of the proof; whilst, on the other hand, it can safely be asserted that gold by itself does not give so agreeable an effect.

There was one point, however, which I felt it was necessary to clear up before pronouncing generally that photographs made upon the present system must of necessity contain silver. This reservation arises from the circumstance of my having employed in former experiments the albumenized paper so commonly used in this country, and which, by my own showing, is apt to retain silver in an insoluble form throughout the process, and quite independently of the action of sunlight. Wishing to exclude this source of error, which becomes important only when a principle is at stake, I have recently taken some prints upon plain salted, *Canson* paper, toning them as before to a full stage by the use of a bath of chloride of gold made alkaline with bicarbonate of soda, and fixing them with hyposulphite of soda. After thorough washing the pure whites of these proofs were found, on testing with sulphide of ammonium, to be absolutely free from silver. A few of these prints were then burnt in separate parcels, the ashes carefully collected and boiled with dilute nitric acid, when, on testing the clear solutions with hydrochloric acid silver was found in every instance. The products were not weighed, but, estimating roughly their amount in comparison with the gold afterwards obtained from the insoluble residues, my judgment would lead me to say that the silver exceeded the gold. There is very little doubt but that these same prints, already somewhat over-toned, would have lost in silver and gained in gold by longer immersion in the toning bath, but the result would not then have agreed with practice; it would merely have furnished evidence of a fact long since ascertained, viz., that metallic silver is capable of withdrawing the chlorine from tetrachloride of gold, reducing the latter to the state of metal, and becoming itself converted into chloride. Dr. Schnauss distinctly states that "it is only pure metallic silver that can accomplish this, and not sub-chloride of silver." From my own experience I cannot controvert this statement, for I have never yet succeeded in preparing the so-called "sub-chloride of silver," and should be well pleased, if it exist, in having an opportunity of investigating its properties.

In conclusion, it may be remarked that this subject was discussed, on the 11th May last, by the American Photographic Society;* that Dr. Van Monckhoven† has already replied to some of the views lately advocated by Dr. Schnauss; and that the gentleman last named did not succeed in producing photographs in pure gold by the employment of a toning bath of *sel d'or*, or of any compound of that metal with hyposulphite of soda.

Chemical Department, Royal Arsenal, Woolwich.

MR. GLAISHER'S AND MR. SPILLER'S PHOTOMETRIC EXPERIMENTS.

BY CHARLES HEISCH, F.S.C.

Will you allow me through your valuable journal to make a few remarks on the subject of Mr. Glaisher's photometric observations, and the admirable note thereon by my friend Mr. Spiller. The result of the experiments detailed by him show what is familiar to all those using Marion's preservative cases, that perfectly dry photographic paper is not easily affected by light, but they do not show whether a dry

atmosphere, apart from its depriving the paper of moisture, is unfavourable to photographic action. The following facts, bearing on this point, may not be uninteresting to some of your readers.

In August, 1854 (the precise date I am ashamed to say I forget), there was one day memorable to all photographers. The sky was cloudless, the atmosphere particularly clear, the sun shining brightly, temperature 85° in the shade, and the air so dry that it was next to impossible to find a dew-point with a Daniel's hygrometer. Notwithstanding the brightness of the light, photography was simply impossible. No length of exposure would blacken paper under a negative, and what is far more remarkable, wet collodion plates which the day after gave with the same lens and under similar circumstances, in the same place, good negatives in 5 seconds, on this day gave only half exposed positives in 1.5 minutes, and negatives could not be obtained. The question of printing might, of course, be due to the dryness of the paper, but the collodion film was wet, so that it would seem as if there were actually less chemical light present than under ordinary circumstances. I would suggest that daguerreotype plates, the surface of which is more perfectly independent of hygroscopic moisture than any other photographic surface we are acquainted with, offer the best means of investigating this interesting question. If a large plate were iodized and then cut up into small ones, uniform surfaces would be obtained. Suppose now a small camera screwed firm on a board with an object (say an engraving) fixed firmly at a given distance from it, and perfectly focussed. One of the small plates might be exposed for a certain time before the ascent, the others for the same time at different altitudes; if thought necessary, equality of temperature might be obtained for each plate by placing behind it in the slide an equal sized plate of copper heated to about 80°. On the return to earth all the plates could be mercurialized together, so as to insure uniformity in this respect. If any great difference were observable in the results it could hardly be due to any drying of the photographic surface, though the dryness of the atmosphere might still be the cause, but in some yet unexplained manner. I should have mentioned that on the day in August 1854, before spoken of, the observations I made were at Blackheath, but my friend, Mr. G. Busk, arrived at precisely similar results on the same day at Tenby.

I cannot conclude without remarking that I believe photographers might, by a few simple observations on the state of the atmosphere while they are at work, arrive at many results valuable not only to themselves, but to meteorologists. Some years since I proposed to the members of the Blackheath Photographic Society, to carry out such a system of observations, and drew up forms on which they could be easily registered, but, unfortunately, though the forms were taken, they were never filled up, so the project fell to the ground, much to my regret. A little combined action of this sort would be a work well worthy of a society, and would entail but a small amount of trouble.

Middlesex Hospital, June 24, 1863.

LIME TONING EXPERIMENTS.

BY V. BLANCHARD.

It will be generally admitted that whilst we have had a great many theories more or less plausible on the alkaline toning process, they have none of them produced that one thing desired by all photographers, viz., a method of producing uniform results, including a panacea which would secure for them some protection against their deadly foe—*mealiness*.

It affords me, therefore, much pleasure to be able to confirm the statements made in describing the method adopted by Mr. Hughes in producing the very beautiful tone I have noticed in his pictures. I have at different times made many experiments with lime toning, but have never been able to produce anything with uniformity, excepting failure.

* *vide* PHOTOGRAPHIC NEWS, Vol. VII. p. 257.

† *Ibid.*, Vol. VII. p. 271.

Some few weeks ago, however, I undertook some experiments which were more successful. I neutralized the gold with carbonate of lime, employing hot water to hasten the decomposition, and then added hydrochloric acid at the rate of about one drop to the grain of gold. A print introduced into the bath was found to tone rapidly, but it bleached at the same rate, and was therefore useless. The introduction, however, of a drop of ammonia stopped this reduction. The prints toned in the bath were black in tone, and were perfectly free from mealiness. I used a bath so prepared for a week or two, for the tones were very satisfactory; but I found frequently that the bath would indulge in fits of sulkiness, and refuse to work at all. This was, doubtless, due to the action of the ammonia, the whole of the free chlorine being neutralized, and chloride of ammonium formed. Doubtless the whole of the uncertainty of the toning process turns upon the difficulty of securing the exact amount of free chlorine necessary at the moment of toning, with anything like regularity.

I also neutralized the gold by various methods; first, trying carbonate of soda; then, carbonate of lime; and, lastly, carbonate of ammonia, but I added to each bath the chloride of lime at the same time; and consequently, when I tried them I found them no better than the others. On the publication, however, of Mr. Hughes's method I saw that the gold was first neutralized, and then the chloride of lime was afterwards added. I, therefore, repeated my experiments, following the plan there suggested, and met with success so complete that I feel it a duty to record it for the benefit of others. The plan now adopted by me after repeated experiments is as follows:—3 ozs. of chloride of gold solution, containing 1 grain to the oz. of water, is poured into an earthen vessel, 9 grains of carbonate soda is now added. It is well stirred until the soda is deposited, and then hot water from the kitchen boiler is poured in, making the whole quantity up to 10 ozs. It will be found, on stirring well, that the whole of the yellow colour will disappear, leaving the solution colourless. It must be now allowed to cool down until the solution is milk-warm, and then 9 grains of chloride of lime must be added, *but not before*. *The whole success of this method of toning depends upon attention to this matter.*

The solution must now be well stirred, and allowed to settle for five minutes, and it is then ready for use. It will be found that the prints, when immersed in the bath thus prepared, tone steadily, but not rapidly, and gradually assume a blue-black of great intensity, and with very little loss of vigour by bleaching. At this point the toning action should be stopped, and the print immersed in water, and afterwards fixed in hypo in the usual way. The tone of the picture when dry and finished will be a clear neutral grey in the deeper half-tones, an intense black in the shadows, and a delicate warm colour in the face, and all the lighter portions of the picture not absolutely white.

In my hands the bath made with carbonate of soda, instead of lime, is most uniform in action, whilst in the finished pictures I can see no difference between them. I must admit that theoretically the carbonate of lime appears best for being insoluble, or nearly so, in water, only as much as is necessary to neutralize the free hydrochloric acid in the gold can be taken up, the rest falling to the bottom, and the solution is consequently only neutral when the chloride of lime is added; but in practice I have found that in using the carbonate of soda a grain or two more or less made no difference, and the solution is brighter, and free from sediment, and it takes a considerable time for all the carbonate of lime to settle to the bottom, and to filter the solution would only increase the trouble without any absolute gain.

It is much to be regretted that the chloride of lime is such an uncertain compound, for it is almost impossible to get two samples alike. It is extremely doubtful if the lime play any part in the production of the black tones, and it is more probable that the peculiar action is due to the loose

manner in which the chlorine is combined with the alkali, and its readiness to depart in search of fresh quarters. I was mentioning this matter to Mr. Crookes, and he suggested the trial of hypochlorite of soda as being a more definite compound, and of the same constitution as chloride of lime.

If this salt should prove successful much would be gained, for it frequently happens that one sample of chloride of lime contains twice as much chlorine as another, and whilst with too little chlorine present the toning will not go on well, and the desired colour cannot be obtained, too much will make itself evident by its desire to restore the paper to its original whiteness.

One important fact must not be lost sight of in adopting this process, that nearly double the quantity of gold is requisite. Of course more gold is needed to tone a picture black by the alkaline method than to tone it brown; but independent of this, there appears to be a more energetic deposit, for it will be found that the bath will work with great vigour for a given time and then stop all at once, and no lengthened immersion will produce the desired effect upon the print.

A CHEAP GLASS-HOUSE.

At a recent meeting of the North London Photographic Association, Mr. Bockett, a clever and ingenious amateur photographer, briefly described a convenient glass-house which he had erected himself upon especially economical principles. We took an early opportunity of calling upon Mr. Bockett, who had courteously invited us to inspect his erection. We found the studio small, but convenient, the folding doors materially increasing the range of distance to which the camera might be removed from the sitter. It was characterised throughout by ingenious contrivance. For instance, a pedestal which was frequently useful as a background accessory was also a cupboard into which was packed a great many of the smaller items of the studio, not desirable to be left about, during the intervals between an amateur's operating. We saw some very good card negatives, which Mr. Bockett had just taken with a very few seconds exposure, which illustrated the facilities for lighting the model, which the room rendered available. We have been favoured with a detailed description of the studio and its mode of construction, together with a schedule of the items of cost, amounting in all to the small sum of £7 ls. 4d. We now append Mr. Bockett's communication.

DEAR SIR,—In accordance with your request I beg to hand you full particulars of my (or rather I should call it substitute for) glass-house. At the foot hereof will be found the quantities and cost of the material, but prior to going into that I will inform you how the matter got about. For five years I managed, with one contrivance and the other, to take my pictures out of doors with simply a projecting screen over the head of the sitter, to moderate the shadows cast by direct light from above; but, as from doing them gratis I found persons were willing to pay (and amateur photography is not all profit); I also found that to produce pictures that would give satisfaction, required some additional outlay as well, as I would add improvement in manipulation.

Now the chief end in view was to make some erection that could be easily removed, not take up too much space, be watertight, and give a range of, say, twenty feet. The first was obtained by having the place built up of sashes, there being four in the roof (which stands due east and west); two in the north side, which is close to a low wall, so that none are required below them, and one large sash on the south side; the remainder of the house being composed, for the most part, of feather-edge boarding; the skeleton to which all the foregoing is attached, being simple 2×2 inch quartering; the joints are covered with canvas, and painted, which has, hitherto, as to keeping out the wet, answered very well. To enable me to get my range, at the eastern side (in which two small windows are placed), I have two folding doors, simply made of beaded boards nailed to some cross pieces, which, opening outwards, give me any distance I may require, and effectually protect the sitter,

accessories, &c., from the weather. Next to the larger sash before alluded to, and near to the folding doors, is another door, in order that access may be obtained to the interior without disturbing the camera or any thing else that may, for the time being, occupy the space between the folding doors.

Some battens, laid edgewise upon the ground, receive the flooring planks, which would have been all the better if closer together and attached at each end to the bottom frame of the skeleton. The folding doors bolt top and bottom, from the inside, and the side door is locked from without, so that all within is properly secured. In the figures below no credit is taken for the labour expended by myself, nor for the contrivance, which simply arose from something of the kind becoming a necessity, and that, being only of limited means, I was called upon to invent something that would really answer my purpose. Constructed as this is, the sashes for the most part being screwed to the ridge piece and sides of the top frame, I believe any one could take it all to pieces in an hour. If the above is of any service to your readers I humbly place it at your disposal.

The shaded part represents wood, mostly feather-edge.

To equalize the light from the south the whole of the large sash is covered with thin calico blinds, and the same with the roof, except that the portion over the head of the sitter, which is covered with paper, the same as used by chemists, and which is known by the name of demy (although I believe the latter only denotes the size).

—Believe me, yours, very truly,

JOHN BOCKETT.

RAPID DRY PROCESS.—FURTHER DETAILS.

BY THOMAS SUTTON, B.A.

In a recent number of the *Photographic Notes* Mr. Sutton gives some further particulars regarding his rapid dry process. He says:—

The process described has been tried by several persons, and with different results. M. Liesegang, of Elberfeld, states, in the German photographic periodical of which he is editor, that he has obtained very fine clear negatives by the process, but requiring an exposure double of that which was necessary with the same collodion and bath, and wet plates. Major Russell stated in the autumn, that he had tried gum some years ago, and given it up because it produced dirty negatives, covered with red fog and blisters, and in which, if you gave sufficient exposure to the foreground, the sky and high lights, instead of stopping short at their outline, ran over it into the other parts of the picture. He stated also, that he had found no advantage in increasing the dose of bromide beyond a certain point, but on the contrary, that the sensitiveness was impaired by so doing. And with respect to sensitiveness, he expressed his belief that his own tannin plates were nearly as sensitive as those prepared with gum. We could not understand at the time the force of his objections, not having experienced ourselves any of the troubles referred to, but we have since discovered that the red fog, and smearing of the high lights, is due to the use of an old worn-out nitrate bath overcharged with iodide of silver, and other foreign substances. But lately the Major's views have undergone some modification, for we find him now recommending bromide alone in the collodion, and mixing gum with his tannin, for some unexplained reason, thereby contradicting in his present practice his former confidently-expressed opinions. We have also received evidence on the merits of our process, of a more favourable character. Captain Hughes, of Everton Valley, Liverpool, has lately written us a note, in which he says, "In your letter which accompanied the panoramic print you recommend me to try your rapid dry process. Your advice was unnecessary. I had been working at it previously. I commenced when I secured your 'Collodion Processes Wet and Dry,' and have been very successful. I have taken perfectly satisfactory cartes in my glass room in 20 seconds. I have had no time for printing lately, but will send you specimens in a few days." Mr. Rowland, of Norwood, also states that he has taken good instantaneous pictures upon dry plates prepared by our process,—and that he has tried mixing the gum with tannin. He adds, "I find that the plates work better with plain gum. I do not like the mixture of gum and tannin, as it gives frequent stains. I do not think anybody could want sharper pictures than the gum gives." And so on. Thus the evidence on the merits of our process, although conflicting, is on the whole favourable, and we hope that those who may have been deterred from trying it in consequence of Major Russell's condemnation, may now be induced to take the matter into their own hands and judge for themselves. The Major's recent experience with gum and tannin seems to confirm that of Mr. Rowland, and if our advice is worth anything, we would suggest him to try gum alone, along with his good old-fashioned bromo-iodized collodion, in which he unconsciously recommends the mixture of bromine and iodine in equivalent proportions,—and above all, a fresh nitrate bath made with the recrystallized salt, and in decent working order. He will then obtain plates precisely resembling in appearance the rapid ones of Dr. Hill Norris; and if he exposes them side by side with the doctor's, he will find no great difference either in the sensitiveness of the plates or the quality of the negatives produced.

These remarks are introductory to an account of some minor improvements which we have made in our process, and some speculations on dry plates generally.

When a preserved plate, which is completely dry in some parts but damp in others, is exposed in the camera, the damp part is much less sensitive than the dry part, and gives a poor, thin image. This is one fact, and it proves that a preserved plate acquires sensitiveness on drying. Again, whether a dry plate is prepared with iodized or bromo-iodized collodion it is more sensitive when it is not thoroughly washed than when gallons of water are poured

over it. This proves that a trace of free nitrate is always an element of sensitiveness; and thus, when the most exalted sensitiveness is required, the plate should not be excessively washed. We are now of opinion that the presence of bromide of silver in the film is not entirely a compensation for the removal of the free nitrate. You may wash a bromo-iodized film tolerably in two or three waters, and find it nearly as sensitive as ordinary wet collodion, but the washing must not be pushed too far if you wish it to be quite equal in sensitiveness to good wet collodion. We have adopted this opinion with reluctance, but it seems inevitable, and the facts cannot be explained without it. If they could, why is a well-washed bromo-iodized plate less sensitive than a less thoroughly washed one? It seems nearly certain that the iodized or bromo-iodized collodion film requires a certain quantity of nitrate of silver to be in close contact with the iodide or bromo-iodide of silver, in order to produce the greatest possible sensitiveness. In the ordinary wet process the silver solution from the bath, which clings to the film, is sufficient. In the dry process, the small trace of nitrate of silver which is left in the film after washing the plate, is not sufficient whilst the plate remains wet; but as it becomes dry, and the water evaporates, this small trace of nitrate of silver becomes concentrated in the neighbourhood of the iodide and bromide, and if that trace in its concentrated state is sufficient, the plate recovers its original sensitiveness, and is not in this respect inferior to the best wet collodion plate. In the case of the wet plate, that portion of the nitrate of silver in the 30-gr. solution that clings to the film which is in actual contact with the bromo-iodide of silver, is enough to confer exalted sensitiveness, while the remainder is necessary to the development. In the case of the dry plate, that portion of the dry nitrate of silver which has been obtained by the evaporation of the weak silver solution which remains upon a washed film is sufficient, by its contact with the bromo-iodide of silver, to confer the same exalted sensitiveness; but there is no surplus for the development.

We are thus able to account for the discrepancies which occur in the experiments of various persons who have recorded their results. No definite or invariable system of washing the plate has been adopted, and that is why some have obtained greater sensitiveness than others with our rapid dry process. And to this may be added the fact, that the great importance of thoroughly drying the plates before their exposure has not been fully acted on, or acknowledged. We now wish those who try our process to proceed as follows:—

The collodion is to be bromo-iodized, containing iodide of cadmium, or bromide of cadmium in the proportion of ten to two. The quantity of these salts used to the ounce of collodion must depend upon the amount of creaminess of film which is desired; and the same consideration must determine the quantity of pyroxylins which is to be contained in the collodion. 6 grains of pyroxylins, 6 grains of iodide of cadmium, and 4 grains of bromide of cadmium give a very creamy film. The collodion which Mr. Bailey manufactures for our rapid dry process does not contain so much iodide and bromide as this; and gives a pale but a very even and delicate film, and is as sensitive as the other, or very nearly so, and gives a softer negative.

The nitrate bath need not be stronger than 35 grains to the ounce, and if you wish for red negatives, which are the easiest and best, add a little acetic acid to it, say six drops to the ounce of solution.

After exciting the plate immerse it in a bath of distilled water, and then in another of rain water, quite clean. It is immaterial how long it remains in the water, but the longer the better, because it is important to remove all the uncombined bromide of cadmium, as well as the nitrate of cadmium, from the film.

The plate must now be placed in a bath of distilled water, containing 1 grain of nitrate of silver to the ounce, or thereabouts,—as well as an equal quantity (one drop) of acetic acid.

After remaining a minute or so in this bath the preservative solution is to be poured over it. The object of the weak bath of aceto-nitrate is to impregnate the film with a definite quantity of nitrate of silver; that quantity being, of course, exceedingly small and the most imaginable trace.

The preservative solution is composed of gum arabic 20 grains, dissolved in water, 1 ounce. A little of it must be poured over the plate and allowed to flow backwards and forwards several times. Then, without pouring it off, put the plate upon a horizontal support, and let the gum soak well into the film for a quarter of an hour before you set it up to dry. This will reduce the tendency to blistering &c., because the gum will soak into the film, and make it stick better to the glass. A small quantity of sugar may be added to the gum, and this renders it less skinny when dry, and reduces the tendency to blistering. By either of these methods a substratum of albumen or india-rubber becomes less necessary. The gum solution should not be stale and decomposed.

The plate must be allowed to dry spontaneously, but before putting it into the slide, it is important to dry it again thoroughly by holding it before a hot flat iron. The heat does not cause the plate to fog, although nitrate of silver is present; this fact is important to have established. Unless the plates are thus dried by heat on the morning before their exposure the result will be uncertain, and the least dampness in the film will be fatal to obtaining a good negative.

The exposure may be the same as for wet collodion plates—that is about 15 seconds to an ordinary well-lighted view, with a stereoscopic view lens 5½-inches focus, and ½-inch stop. With the ½-inch stop instantaneous views of clouds and waves may be got in a good light.

The development is effected with cold pyrogallic acid and silver, exactly as recommended by Dr. Hill Norris, without any ammonia, or hot water, which would only end in grief and vexation.

It is always surprising to us that persons are so ready to run after all sorts of queer novelties in the development, and at the same time ignore the fact that Dr. Hill Norris' rapid dry plates have never been surpassed in sensitiveness, and are at the same time developed in the usual simple way. How unreasonable it seems in any investigation to go on groping in the dark after novelties, and at the same time ignore the fact that the very thing of which you are in search has already been done in a known simple way. Is it not more reasonable to avail oneself of what has been already done by the labours of others, than to grope in the dark and try to do the same thing in a different way? If Dr. Norris has proved, as he has done, that rapid dry plates can be satisfactorily developed in the usual way with cold pyrogallic acid and silver, why bother about the ammonia, the hot water, &c.? Why not accept his method of development, and try to discover how he prepares his plates? That is exactly what we have done. We have tested his preservative, and find it to be gum arabic. We have tested his plate and find it acid, and also that it contains a trace of free nitrate. It has, moreover, the property of becoming more creamy and opaque when wetted with the finger, exactly as our plates have, and its colour is the same, as well as its behaviour when exposed to light, and when rubbed about upon the glass. Dr. Hill Norris has been our guide in the search for a rapid dry process. We have endeavoured to find out his secret, and to all appearance have succeeded. Those who wish to give our process a fair trial must follow our directions implicitly, and compare their plates, as well as their negatives, with the Doctor's plates, and the negatives obtained upon them under the same circumstances. Let them not try impatiently too many things, and go running after fresh novelties like so many children, experimenting with hot water on day, ammonia the next gum and tearin the next, and trouble with wet iodide the next. All this is so much groping in the dark. Let them rather accept the demonstrated fact of

what Dr. Hill Norris has actually done, and endeavour to work up to the same result by the aid of such light as our experiments have afforded, and such reasons as we are able to give for every stage of the process which we recommend. If the Doctor has really accomplished all that we say, and if our process yields plates so exactly like his in all essential points, as we assert that they do, then surely the best advice that anyone can offer on this subject is to try the process which we recommend before any other.

With respect to the keeping properties of rapid dry plates, the evidence which we have collected during the last few months is not such as to enable us to recommend them to be prepared many days in advance. We would not, on any important occasion, willingly use any dry plate which had been prepared longer than on the previous day, or which we could not develop on the day on which it was exposed. There is, according to our experience, great uncertainty in the use of any dry plates which have been long prepared. Exceptions occur, of course, but we believe our statement to be the rule. It is a deplorable pity that it should be so, but so it is, and the fact accounts for the very small number of pictures from dry plates which are seen in the Photographic Exhibitions. A week or two for slow plates, and a day or two for rapid ones seem to be the extreme limits of certainty, if the plain truth must be told. You may get a negative upon a dry plate a year old, but seldom a perfect one.

THE PREPARATION OF COLLODION.

BY DR. F. FUCHS.*

PERHAPS for no article used in photography does there exist such a variety of formulas, and each one looks for the cause of failure in something else. The following is in my hands always free from failure. The problem of the preparation is simply solved, as will be evident from the formula. For several years in succession, and when operating with two pounds, I have never spoiled the lot nor have had any mishap with it. I took a large vessel and weighed in it 40 pounds of English commercial sulphuric acid, to this I added 18 pounds of pulverized English crude saltpetre, and stirred the mixture with a wooden spatula for ten minutes or so; to this mixture I now added quickly 2 pounds of cotton in light tufts as large as the first, whilst an assistant brought them in contact with the fluid. The mixture is sufficiently thin to allow the cotton to be easily pressed down with a spatula. I let the cotton remain in the mixture until a small piece, after washing with water, pressing, soaking in alcohol, and again pressing, was easily and completely dissolved in two parts of ether and one of alcohol. Until this takes place the cotton is not ready to take out.

When it has reached to this degree of solubility, it is taken out with the spatula, immersed in a large tub of water, and thoroughly washed. It is then taken out in one mass and pressed between folds of linen; after this it is put into a vessel, covered with alcohol, and allowed to remain in this condition for 24 hours. On the following day the deep yellow-coloured alcohol is poured off and totally removed by pressure. Whilst the cotton is still moist, for every single part add two parts of alcohol, and then from 15 to 20 drops of concentrated ether. By this means a colourless, excellent collodion is obtained without failure.

I used the best cleansed cotton, such as is met with in wadding factories, and found it in a great measure yellow, a colour which was afterwards communicated to the collodion. By the above method the yellow colour was removed.

Treating cotton with soda is unnecessary. Ordinary English sulphuric acid is sufficiently strong, and English saltpetre is good enough for the purpose. The latter is used in quantity less than any other known formula, and the great superabundance of sulphuric acid renders the mixture

very fluid, and allows a greater quantity of cotton to be immersed without being detrimental to its quality. By making use of a wooden spatula, which simply assumes a yellow colour, we avoid the risk of breaking a glass rod or the vessel. It is, besides, easier to work with a wooden than a glass rod. Every other formula indicates exactly the time during which the cotton has to remain in the mixture. This depends in a great measure on the temperature and the strength of the cotton fibres. In summer ten minutes is sufficient time for the reciprocal action of the saltpetre and the sulphuric acid, before the cotton is immersed. In winter the vessel containing the mixture must be placed immediately in warm water, before the cotton is introduced, otherwise the fluid, by the formation of bisulphate of potassa in the cold, will become too thick, and the given quantity of cotton cannot be immersed. If abundance of red fumes arise, and these cannot be obviated by pressing the cotton beneath the surface of the mixture, a small quantity of sulphuric acid may be added without any injurious effect upon the product, on which the fumes will immediately cease.

The transition of soluble cotton into insoluble is not quick, and there is sufficient time to make the requisite test. As soon as the cotton has attained its solubility, it is taken out of the vessel, and the acid is well expressed before the cotton is washed. The fluid that remains can be used over again very well in large quantities, when prepared with nitric acid. The cotton must be thoroughly freed from all trace of acidity, which is recognised by the taste and by treatment with litmus paper.

Good pyroxyline, when being washed, feels soft; whilst insoluble pyroxyline, when separated in a moist state, cracks in the fingers and is often corroded. I allow the washed and pressed pyroxyline to remain over night in alcohol, which totally removes the yellow colouring matter, by which proceeding the collodion becomes colourless. The residual alcohol can be used for a lamp. I dissolve the cotton while moist, in order to spare the trouble of separating the tufts and drying. Alcohol 90 per cent. is sufficiently strong, as also concentrated ether of the specific gravity of 0.73.

Recent Patents.

ORNAMENTAL PHOTOGRAPHIC BORDERS.

THIS invention, which received provisional protection only, was a communication from Monsieur Henri Lissagaray, of Paris.

The invention is thus described:—

These improvements relate to the ornamentation of photographic works, and chiefly to the production of backgrounds, borderings, and such like aids to the art of photographing objects. For these purposes I produce the design required by employing a sheet of glass or other equivalent transparent substance, upon which, by galvanic agency, I deposit first a coat of gold or other metal suited for the purpose, and next a coat of platina or other equally suitable metallic surface. I then engrave, by means of a stile or point, the required ornamental design, so that the light may pass through the lines so marked, engraved, or cut into or through the metallic surface. An open space may be left in the centre or other part or parts of the plate prepared as described, so that a portrait or portraits, or other subject or subjects intended to be reproduced may be introduced behind or before such space, or otherwise in combination with such engraved plate.

This process, when used for ornamenting photographic proofs, is employed by means of double stereotype plates of glass or other equivalent transparent substance prepared as described, and used together by superposition or in succession. The effect may be varied by the variations in the depth as well as the width of the lines engraved or etched upon, or cut through the metallic coating of the transparent ground, and in accordance also with the intensity of the light employed, and compound figures and effects can be produced by the intersection of more than one prepared plate used in combination with any other.

APPARATUS FOR VIEWING PHOTOGRAPHIC PICTURES.

This invention, known as the Alethoscope, by J. Ponti, received provisional protection only.

It consists in constructing an apparatus for viewing photographic pictures, resembling generally in form that of a "stereoscope," but of considerably larger dimensions, and provided with only one large magnifying lens, and only one representation of the picture (which is also of considerably larger dimensions than those employed in "stereoscopes"), the object of the invention being to present readily to both eyes of the observer, without the inconvenience of looking through two separate lenses, a representation of the picture magnified to such an extent, and at the same time having the stereoscopic effect sufficiently to impart to the same the appearance of the object itself in its natural size. The lens of this apparatus is, by preference, made of such a size as to take in conveniently the sight from both eyes of a person, and a shade surrounding the lens is made to project from the same towards the observer, to prevent the eyes taking in any other rays of light than those passing through the lens; this is also so arranged with adjusting screws, that it can be brought nearer to or moved farther from the eyes, according as the difference of sight requires it.

This apparatus is arranged in a horizontal position on a suitable stand, the picture being in a vertical position, and the end of the apparatus where the pictures are inserted being, by preference, made of an oblong form, provision being made for causing it to revolve round a horizontal axis to such an extent, that in one position the larger dimensions of the picture is horizontal, whilst in the other direction it is vertical, so as to suit pictures of different proportions. The apparatus is arranged for viewing either transparent pictures or pictures requiring a reflected light, for which purpose it is constructed in the following manner:—A portion of the top and side of the apparatus, near the end where the pictures are inserted, are made to open on hinges, and are provided on their inner surface with reflecting mirrors in such a manner as to reflect the light (which may be either artificial or natural, and is, by preference, situated behind the end surface of the apparatus), more or less on to the picture, according as they are adjusted in position. The light is then reflected from the picture through the lens to the eye of the observer. For transparent pictures the two before-mentioned reflectors are closed, and the end opaque surface of the apparatus (which is also provided with hinges) is let down, so that the light passes through the picture. The frame for holding the pictures at the end of the apparatus is, by preference, made curved in such a manner as to cause the picture to be slightly concave when inserted, to suit the form of the lens. In order to prevent the bright light (particularly when it is artificial and situated at the back of the apparatus) from blinding the eyes when one picture is removed for the purpose of inserting another, a more or less opaque flap is provided close behind the lens, which, by means of an external lever, is instantaneously raised in front of the lens when the pictures are being changed.

Another part of this invention consists in preparing photographic pictures to be employed in this apparatus in such a manner that they shall be capable of representing, consecutively, both a day and night appearance of the object. For this purpose the photographic picture is made on paper, or other suitable material, that will both reflect the light and yet be transparent to a certain extent, and is provided at the back with a sheet of transparent paper, or other suitable material, that is coloured with transparent tints representing the effect of night, moonlight, or artificial light, in a manner corresponding to the objects on the picture. By this arrangement, if such pictures are inserted in the before-described apparatus, the back of the same being closed and the two reflectors opened, the light will be reflected on to, and from, the surface of the picture, as before described, and a daylight effect will be produced: whilst, if the two reflectors are then closed, and the back of the instrument opened, the light will pass through the tinted back, and through the picture itself, and the night effect will thus be produced.

PREPARING PAPER FOR THE TRANSFER OF PHOTOGRAPHIC PICTURES.

The subject of this patent is a communication from Jean Théodore Dupuy, of Paris. It was sealed the 19th December, 1862.

This invention consists in a method or methods of preparing paper for the reception of photographic pictures, in order that the said pictures may be transferred to and fixed on wood, porcelain, and other surfaces, all as hereafter explained.

First operation.—Take a sized or unsized gelatinized, albumenized, or cercolinized (cercoliné) paper, (if the paper is not sized it is covered with size, starch, glycerine, or other sizing material), cover it with a solution of ammoniacal citrate of iron and bichromate of ammonia, and dry in a dark chamber. Or the paper may be prepared with the different salts of iron and chrome, with perchloride and lactate of iron, with potassic citrate of iron or manganese, with pyrophosphate of iron, with potassic or ammoniacal tartrate of iron, with bichromate and chromate of ammonia or potass, with the addition of gum gelatine, sugar, or albumen, or Judea bitumen developed in a solution of oil of naphtha and benzine.

Second operation.—The paper prepared by one of the means just described is submitted to light printing in an ordinary photographic printing frame.

Third operation.—The impression or print obtained is submitted damp, say, by exposure in a damp cellar, or to damp steam, breath, or any other suitable damping agent.

Fourth operation.—The dampness condenses on those parts which have not received the impression of the luminous rays. I then colour the print with a vegetable or mineral colour in a state of fine powder, according to the purpose for which the print is intended. Sometimes I apply powder of gold, silver, or other metal.

Fifth operation.—To fix the powder on the print, it is covered with a varnish, such as collodion, benzoin, and ether, varnish, gum lac, caoutchouc, gutta-percha, Judea bitumen, cereoline, copal, gum arabic, dextrine, gelatine, and all boiled oil varnishes and resinous substances dissolved in alcohol, ether, turpentine, chloroform, or ammonia. In some cases I cover the glass with collodion iodized and sensitized with nitrate of silver. After the operation in the dark chamber, or in the printing frame under a negative, the print or impression is developed in a solution of iron or pyrogallie acid; it is afterwards fixed by hyposulphite of soda and cyanide of potassium, the print being washed and placed on a gummed, gelatinized, albumenized, or waxed paper. The picture fixed upon this paper may be transferred as may be desired. To shorten the operation before described, I sometimes cover a glass with collodion chloruretted and sensitized with nitrate of silver, and dry it in the dark, to be used as required. It is afterwards placed in a printing frame under a negative, and fixed by hyposulphite of soda. I wash the print, and cover it with one of the varnishes described under the fifth operation, and then with a gummy varnish.

After the preceding operations have been performed I colour the prints with a brush with mineral colours, if they are to be transferred to surfaces which undergo firing to fix the colours, such as porcelain and earthenware, or with vegetable colours if the prints are to be transferred to wood, leather, or to any other substance not requiring firing to fix the colour. The colours instead of being laid on with a brush may be produced by lithographic or typographic printing.

All photographic prints obtained according to this invention on paper prepared as before described may be transferred to all sorts of objects. Varnish and rectified essence, brushes, a piece of cloth, and a paper knife are all that are required to effect the transfer. To transfer a photograph printed on paper prepared as before described, dip a brush into transfer varnish, and give the picture a thin coating of it; then place this picture with the prepared side downwards on to the object to which it is to be transferred, care being taken that it occupies its correct position when first placed, in order that friction may not afterwards injure it. Next, cover the paper with a piece of slightly damped cloth, and with a paper knife or other convenient instrument rub evenly over the cloth to fix the print on the surface to which it is to be transferred. The cloth must not be too wet, yet sufficiently so to saturate the paper. The cloth is next raised, then with badger or other suitable brush wet the paper with water, and in a very short time it may be removed or peeled off, when the photographic print will be found transferred to the surface on which it was placed, the paper having no trace of it left. The preparation on the print may be afterwards washed off with a soft brush or sponge, and blotting paper may be applied to remove any wet from the print. When the print is thoroughly dry, it should receive a thin coat of varnish.

THE FUMINATING PROCESS.

THE "fuminating process" is the name given to the method of fuming sensitive paper with ammonia. In this country the method does not seem to "take;" but in the States it seems to be gaining general adoption. The following description of the method employed is given by a correspondent of *Humphrey's Journal* :—

"The following brief description of the fuminating process in printing photographs may interest a small portion of those that semi-monthly peruse the pages of your spirited journal. The origin of this process for neutralizing the traces of acid in silvered paper is not of recent date, but may be traced back to the very beginning of photographic printing in this country. As long ago as the summer of 1853 Mr. Duchochois and myself used the ammonia vapour bath, very similar to those used now, and with the same results. At that period, however, the demand for photographs was very small, and the process being tedious on a small scale, we discontinued it, and adopted the ordinary ammonio-nitrate process, which has been very generally used up to the latter part of 1862. If I am correctly informed, Mr. Hugh O'Neil, operator for C. D. Fredricks & Co., was the first to revive the use of the vapour bath, and began using it successfully about one year ago. Since then others, and nearly all in New York, have used it more or less generally with good success.

"There are various modes of constructing boxes or dark chambers for fuminating purposes, of which one is a high box divided in the centre into two chambers by a perforated partition, the upper chamber being provided with cleats and pins, on which several sheets are hung at a time. The ammonia is poured into an open dish and set on the floor in the centre of the lower chamber, the perforated partition serving as a distributor of the ammonia vapour. After the paper has been properly arranged in the upper chamber and the ammonia^o fortis in the lower as described, close the box tight and subject the paper to the vapour for ten minutes; then remove it for use, not allowing it to come in contact with strong solar light. Before vapourizing, the paper must be silvered in the ordinary way, excepting that the silvering solution must contain 60 grains to the ounce instead of 80 or 90 grains, with just enough ammonia to keep it from discoloring. Another mode of making a box is with only one chamber, and opened at the top by means of a door or cover on hinges. The opening in the top is required to be the size of a sheet of paper, having slots countersunk with pins at each corner to hold the paper. By this arrangement a piece of cotton flannel, the size of the box, is saturated with ammonia fortis and spread in the bottom of the box. A sheet of paper is placed on the pins at the top, silvered side down, and the top or cover carefully shut, and left so for two minutes; then raise, by means of a string, a trap door so constructed as to close up under the sheet of paper to prevent the escape of ammonia while changing the sheets. The trap door being closed, raise the outside door or lid and remove the fuminated sheet, placing another on in the same manner as the first, and so on, cautiously avoiding exposure to light."

MAGIC LANTERN SLIDES.

BY H. T. ANTHONY.*

As a great deal of interest is at present manifesting itself in the use of photographic transparencies in connection with the magic lantern, and as transparent positives made by means of the ordinary wet collodion process do not seem to be of a character well suited to this purpose, it has occurred to me to suggest one or two dry processes which in my hands have produced transparencies in my opinion excellently suited to it.

* *Amateur Photographic Print.*

The first is a process which has long been described in the journals, but which, as far as my experience extends, has never met with the favour it merits. It is as follows :—

"Take any good working bromo-iodized collodion, sensitize in the ordinary acetic acid silver bath and wash well after removal from it. Then flow over it a three-grain solution of chloride of ammonium, say for one minute, and wash well again. Finally flow upon it for the same length of time a two-grain of freshly dissolved gallic acid, rinse off and dry. Expose in contact with a negative and develop with pyro and silver in the ordinary manner."

Another process which is characterised by great quickness and ease of development, consists in making use of the ordinary fifteen-grain tannin solution preservative merely modified by the addition of three drops of the purest glycerine to the ounce.

I have made positives by this latter process hardly distinguishable from albumen. The plates prepared in this manner I have found excellent for negatives, being very sensitive and giving more detail in the shadows than the ordinary tannin plates.

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, July 1st, 1863.

At the last meeting of our Photographic Society M. Davanne presented two photographic pictures on paper which had been submitted to the test of exposure in two Exhibitions (1861 and 1862), and which showed no signs of fading or alteration whatever. This, then, may be accepted as a satisfactory proof that photographs, when carefully prepared, are permanent. For the pictures in question were submitted to the severest tests that photographs are ever likely, to be exposed, the conditions being every variation of light heat, moisture, &c., and they remain as fresh and pure as at first. It was also remarked that photographs are more liable to change when kept in a portfolio than under glass exposed to luminous action. A sulphurized proof, if kept in a perfectly dry place, remains for a very long time without exhibiting any signs of alteration, while in a damp place change is immediately evident. Thus, a photograph carefully framed is much better sheltered from humidity than when kept in a portfolio.

M. Rollo presented to the Society a photographic reflector of pure silver, which by neutralizing violent contrasts, admits of our obtaining excellent results in the worst constructed operating rooms, and at hours when exposure was previously impossible; besides this, it gives new and wholly unknown effects, and it may be employed with great economy in enlarging as a powerful reflector of light. It measures forty-eight inches square, weighs about eight ounces, and may be stretched on a frame or on a roller.

Mr. Herman Krone made the following communication upon the preparation of a xyloidine collodion which he calls *nitramidine*. He says: "I have undertaken to prepare a collodion *a la nitramidine* (xyloidine) in order to show the manner in which this body acts in photography. Starch, dissolved in nitric acid, was precipitated by water [C¹² H⁹ (NO³) O¹⁰] (Pelouse). By operating with various proportions of alcohol and ether, we obtain a collodion entirely devoid of coherence in its normal state, without iodine, it dries under the form of a white and opaque film, very adherent to the surface of the glass, viewed through the microscope it appears like a cracked crust. Prepared with iodide of cadmium, this film cracks more than with the other iodides used, it appears like a ploughed field furrowed in every direction. From its want of coherence perhaps this collodion is very slightly photogenic; it requires six times the ordinary exposure. During the operations of developing

fixing, and washing, the surface breaks up piece by piece, in spite of the minutest precautions.

M. Victor Cassaignes exhibited a stereoscope with coloured glasses, upon which he remarks:—

“Objects present themselves to our observation not with their peculiar colours merely; they assume also a general tint resulting from the reflections of other coloured objects falling upon them, or from coloured diaphanous films which intervene between them and our eyes.

The hues under which we see objects in winter or in cold countries differ notably from those with which they are clothed in summer or in warm countries. And the same differences or the greatest contrasts occur at different hours of the day, even when not modified by factitious light, such as the light of a conflagration. Thus, in nature, the same picture presents very different aspects, according as it is viewed in the morning, at noon, or at evening, by sunset or moonlight, under stormy clouds or a clear sky. Still the objects remain the same, and these changes in their aspect are due only to the variations of light. It is these general and delicate hues of nature that M. Cassaignes has sought to imitate in the stereoscope.

He believes that the stereoscopic lenses may be made coloured, or plane coloured glass may be placed over the white lenses, or any transparent coloured films, such as gelatine, may be substituted for the glass. Then the pictures viewed through these stereoscopes will become chromo-stereoscopic, acquiring the colours of the glasses or diaphanous films. The finest effects of light we see in nature may be imitated by this means, and the first advantage of this colouring consists in correcting the snowy aspect which disturbs the harmony of our present stereoscopic views.

By numerous experiments upon the new fixing agent—sulpho-cyanide of ammonium, M. Lewitsky has recognized the solid advantages of this new mode of fixing. MM. Garin and Co., manufacturing chemists, announce that they are prepared to supply the new fixing salt at four francs the kilogramme, equal to eighteen-pence the pound. As the baths require to be saturated solutions, even at that price this fixing solution is very costly. It is to be hoped that manufacturers will be able to reduce the price upon an increased demand arising.

Photographic Notes and Queries.

WERGE'S PLATE CLEANING SOLUTION.

SIR,—I can quite support your recommendation of this preparation, so far as its immediate effect on the plate is concerned; but I think those who try it ought to be cautioned that it certainly contains nitric acid, which, if allowed to be in contact with the fingers for any length of time, may produce troublesome sores. The use of india-rubber finger tips would prevent this. But there is another inconvenience which will be felt by those who use a neutral bath, viz. that a slight trace of acid probably remains on the plate when it is apparently quite clean.

On the whole, I have found nothing so safe (or more efficacious) as the use of old collodion on cotton wool after thorough and careful washing.—I remain, Sir, your obedient servant,
A LONDON AMATEUR.

[We believe all plate cleaning solutions contain acid, and care should be used not to allow the fingers to come much into contact with the solution, and also to polish every part of the plate especially the edges, with a dry cloth, or tuft of cotton wool.]

IRON DEVELOPMENT WITHOUT ACID.

SIR,—Seeing the letter of Mr. Bartholomew in your last on the above subject, I can add my experience as to the possibility, under certain circumstances of working iron salts without acids. About 18 months past I was engaged taking some pictures, and being much troubled by the necessity for unusual length of exposure in the camera, I found on testing that my bath had become very acid. Having no other at hand, and desiring if possible to obtain pictures at once, it struck me that by reducing

the acid in the developer I might to some extent neutralize the extra acidity of the silver bath. After several attempts with increasing success, I tried at last the use of the sulphate of iron alone, and to my great satisfaction obtained pictures full of tone and detail, with very much less exposure. I was using Ponting's simply iodized collodion with acetate in the silver bath; the pictures produced when the light was at its best requiring no re-development. There were no symptoms of fogging, but bright, clear, full-toned negatives: the developer remaining on the plate for a few seconds without apparent effect, when the pictures suddenly started out at once and did not appear to be much improved by keeping the developer longer on the plate.

I have never tried the simple salt with a nitric acid bath, but, theoretically, I should not expect it to prove so successful.—
Yours respectfully,
E. E. L.

ERRATUM.

DEAR SIR,—Allow me to point out a misprint in the NEWS of the 26th instant.

In your account of Dr. Kemp's dry process, No. 3, you say the two halves of a stereoscopic plate had respectively ten *seconds* and twenty *seconds* exposure in his drawing room, with a Dallmeyer's stereoscopic lens, No. 4 stop, on a dull day in December, page 303, line 8 from top of right hand column. On referring to Dr. Kemp's book (page 43), I find he gives the exposures as *minutes*, not *seconds*.—I am, yours truly,
JOS. S. HURST.

[We are obliged to our correspondent for pointing out this error of the press. Of course ten seconds would have been very much insufficient under the circumstances named even with the most sensitive wet plates.—Ed.]

Talk in the Studio.

PHOTOGRAPHY IN TASMANIA.—The *Weekly Times*, published in Hobart Town, proposes to devote a column weekly to the advancement of photography in Tasmania. Correspondents will be answered by a competent person. One of the especial objects will be the formation of a Tasmania Photographic Society. On the subject the editor of the journal in question says:—“We are sure there are a sufficient number of professionals and amateurs to make such a society both successful and valuable. ‘Union is strength,’ and in this case ‘Wisdom;’ nothing would so conduce to the advancement of the art as mutual assistance and encouragement. In England the Societies of this nature embrace all classes. The Heir to the British Crown has become the patron of the London Photographic Society, dukes, duchesses and the nobility of all ranks are numbered amongst its members down to the photo's assistant. Why should otherwise than a gentlemanly mien and intelligent capacity be the qualification for membership? Can we not break through the party walls of station here? Can we not raise photography to the same standing as the other colonies? Excite a generous emulation amongst those who will take an interest in it, and depend upon it, marked results will follow. We surely have sufficient intelligence amongst us—and have exhibited energy enough in the matters which have before engrossed our attention—let the thing be commenced by a few who have a life interest in the matter—a determination to create success, and their ranks will soon be swelled by many who never before were engaged in so beautiful a science. If this be carried out, who knows but that Tasmanians may be looked upon as authorities, and our humble island home be regarded as a seat of learning.

GLUE FOR INLAYING METALS.—To a pint of common dissolved glue used by joiners, add two table-spoonfuls of pulverized resin, and a like quantity of brick-dust. Another preparation of glue for the same purpose consists of a pint of dissolved glue, one ounce of dissolved isinglass, and two ounces of vinegar. Strong glue and fine chalk powder mixed with it is used for cementing ivory to wood.

HOW TO PREVENT FORGERY OF BANK NOTES.—A new idea, to prevent the forgery of bank notes, &c., has just been started. It consists in using a single sheet formed of several layers of pulp, superposed, of different nature and colours, according to requirements. The check it gives to alterations of documents is excellent. It only requires that the middle layer be coloured of a delible or destructible colour. The chemical acid employed

in obliterating the writing will also destroy this colour, which cannot again be restored while the paper surface remains white.

FORMIC ACID.—Mr. Warner in a recent letter says:—I beg to add my mite to the information on this point. To-day I took a negative during a heavy thunderstorm with it, the exposure being four seconds. The developer was as follows:—

Saccharo-sulph. ferri	150 grains
Acetic acid	150 minims
Formic acid	1 drachm
Water	5 ounces
Alcohol	quantum suff.

I got a rich negative with the pyro and formic acid, same exposure, a thin grey, under-exposed image. I quite agree with Mr. Cooper that the iron and formic acid is the best of all.

PATENT ALBUMENIZED PAPER.—The same correspondent says:—I can speak very highly of Sutton's india-rubber paper. I bought a ream the other day of a celebrated maker which is so bad, that I intend returning the remainder.

To Correspondents.

D.—We have submitted your queries to Mr. Blanchard; the following are his answers: 1. This method is not available where thin metallic images are produced. Such negatives must be intensified by some other method. Try a different sample of collodion. In order to produce the best result a rich creamy looking negative is needed to begin with. If, however, after intensification the negative, when dry, appear too thin, the application of bichloride of mercury, saturated solution in cold water, followed by a very weak solution of iodide of potassium, say 2 grains to 1 ounce of water, will bring the negative up to the mark. 2. I have never met with this difficulty but once, and it was then caused by the admission of white light. 3. The plan suggested last week is best.

A SUBSCRIBER FROM THE FIAT has some friends who wish him to take their portraits with their heads under their arms, and he wishes to know how the matter can be managed. We have not seen any such grotesque portraits, but we can conceive it quite possible to produce them by the system of double printing, the exact details of which must be governed by the precise design. 2. If the only disadvantage which age has induced in the collodion to which you refer is thickness, you may dilute it either with new thin collodion or pure ether. If, however, it have become decomposed and insensitive, it may be utilized for cleaning plates. 3. As a rule it is better that the nitrate of silver for the bath should be recrystallized.

A. Z.—From the spots in your sensitized paper always occurring near the corner by which they are pinned, and from the fact that in one of the samples sent a mark, as of the edge of a board, is apparent, it seems likely that you pin them to a piece of wood which is not clean, and where the contact is close spots and stains are produced. This is the only reason which at present occurs to us.

A BELIEVER IN THE OPINIONS OF THE PRESS.—The print just received is a very good one. From what you now state as to your capability to prepare and keep in order your own solutions as well as manage all the manipulations, we should conceive that you will have little difficulty in obtaining an engagement as printer.

C. DE V.—You had better not change the positions of your lenses. They will work best as they are.

D. G. LINES.—Of the two named we should prefer the first, as having the greatest reputation. You can doubtless get them genuine of the house you name.

TYRO.—We cannot speak with absolute certainty of the cause of the poor feeble effect in the prints received. We should have been disposed to attribute much to feeble or forged negatives, had you not stated that the negatives are brilliant. A stronger silver bath, and printing in the shade would, however, have doubtless produced better results.

YOUR PHOTO.—Steadily persevere and you will improve. It is always desirable to complete the operations of exciting, printing, toning, and fixing in one day, if possible. The operations may, however, be delayed for a day or two if the sensitive paper be kept in a dry, dark, cool place. It will not, however, tone so well, or give such good results. Your best method of obtaining a negative will be to go to some good professional photographer, and sit for your portrait, and then purchase the negative. In the print received the paper has either moved in the printing frame, or the camera has been shaken in taking the negative, so as to slightly move everything. You must print and tone deeper.

A READER.—We have met with the troubles you describe with some samples of the enamel paper, but not with all. In most cases the small blisters to which you refer disappear, and leave no trace after drying. The best remedy we have found when the tendency exists, is the use of a stronger silver bath, slightly acid with nitric acid. A good remedy, however, will be another sample of paper. We have generally noticed the streakiness of which you complain, and the tendency to blisters, to belong to the same sample.

HYPO.—The sole cause of the stains in your prints is carelessness or slovenliness in manipulation. The brown looking stain, metallic when viewed in a certain light, is, almost without exception, the result of hypo coming into contact with the print before it is fixed, either when in the printing frame, or whilst washing or toning. If the print be touched with fingers which have been in contact with hypo, and not thoroughly washed afterwards, such stains are certain to be the result. Some persons adopt the very bad plan of fixing some prints whilst others are toning, and it is almost impossible, under such circumstances, to avoid causing stains. The best plan is to complete the printing for the day; then wash all the prints; then tone all, placing each print in a dish of water when done, and then fix all, taking care to lift each print from the water with one hand and drop it into the hypo; then with the other press it properly into the solution. But the fingers which have touched the hypo must never touch the unfixed print, not even to lift it into the hypo.

N. G.—If you send us one of the prints which turn yellow we shall doubtless be able to suggest the cause; but your description is too indefinite to enable us to state without seeing it.

P. T.—After the addition of such a variety of things in indefinite proportion to your toning solution, it is difficult to say what was its operation, or why such and such results followed; in any case your description is not sufficiently precise to enable us to form an opinion. 2. You must cultivate a habit of greater precision. You now leave us altogether in doubt as to the real object of your question. There are several printing processes in which dichromate of potash is used; but you do not state which of them it is, regarding which you require information. One process, headed "Iron Printing Process," appeared in our last. We shall always have much pleasure in giving any information or advice you require; but you must endeavour to be clear and precise in stating your difficulties or requirements.

CUR RESCIAE PUDENS.—A hypo bath would probably have a solvent action on a film of varnish. 2. Sometimes soaking in water alone, especially hot water, will remove the film from varnished plates. A solution of carbonate of soda, or carbonate of potash will readily affect it. 3. The silver bath would probably not be affected by immersing a single varnished plate. 4. Collodion which has lost its fluidity from loss of ether can be put into working condition by the addition of ether. 5. It is not necessary to add chloride of sodium to the bichloride of mercury. 6. When intensifying with bichloride of mercury you may work in a strong light; but it is desirable to avoid a strong light when intensifying by depositing silver, whether it be done before or after fixing. 7. You may return the solution of bichloride of mercury from the plate to the bottle; but remember it gets weaker with use. 8. As you must use a very weak solution of iodide of potassium it rapidly becomes exhausted. It may be used once or twice over, but is generally by that time exhausted. 9. See answer to No. 6. 10. The plate has been imperfectly washed, and so caused irregular action. 11. If the gold is not precipitated add carbonate of soda gradually until the solution is neutral, and then try. 12. Prints from weak negatives often appear to lose more in toning and fixing than prints from vigorous negatives, simply because they do not permit of such perfect reduction in printing without destroying the whites. 13. There is no certain guide to perfect fixing except the use of fresh, strong hypo, and sufficient of it. In some cases the appearance of the print, when examining by transmitted light, having no opaque patches of chloride of silver, may aid the judgment; but it is not a certain guide. Read the chapter in our last ALMANAC on the subject.

A SUBSCRIBER.—From your description it is clear that nitric acid in excess is the cause of your trouble. A large quantity of nitric acid in the silver bath would make it give good positives as you describe; but would make the negative image thin, grey, and metallic. Add a solution of carbonate of soda, a little at a time, until there is a very slight permanent precipitate, the bath will then be neutral. In using litmus paper for testing simply touch blue litmus with the bath, if it turn purple the bath is slightly acid, if it turn more red it is still more acid; if it become a bright red immediately there is a large amount of acid. To test for alkalinity use the reddened litmus paper. Take a piece of blue litmus and hold it over the orifice of a bottle containing acetic acid. The fumes will redden the litmus paper. Any alkaline solution now touching the paper will cause it to become blue. Adding no silver to the developer is a sufficient reason for getting no picture with the majority of dry plates.

CONSTANT READER.—The cause of the meanness is probably too rapid toning and the use of a newly mixed toning bath.

T. G.—With a portrait lens of 11 inch focus from the back you ought to be able to obtain a satisfactorily defined group of 7 or 8 persons on a whole plate, if the lens be good for anything at all. The best plan is, if possible, to arrange the group in a semicircle to suit the curve of the lens. The triple is the best lens we know for groups, but it would not, of course, be so rapid as a portrait lens. Working in the open air, you can probably afford to reduce the size of the stop in the portrait lens, and that will aid you. Please send us one of the prints to examine. We shall have pleasure in receiving the communication to which you refer.

G. J. F.—As a general rule, about 15 grains of protosulphate of iron give good results. In such case use the same proportion of acetic acid. It is not necessary to increase the proportion of acid in the same ratio as the iron.

M. B.—There is an unquestionable difference in the appearance of negatives fixed with cyanide. They are not so brown and non-actinic as those fixed with hypo.

S.—We cannot recommend you to take a patent. Few photographic patents pay, and what we have seen in your results would not justify you in going to the expense of a patent. We think the use of blue glass for lenses a mistake. White glass will permit all actinic light to pass; blue glasses can do no more, but it is quite possible they will do less.

JOHN ALEXANDER.—In reference to the preparation of formic acid, we may remark that if you are familiar with chemical manipulations, the following proportions will aid you, perhaps, in producing the acid. This method of producing this acid is only of recent introduction. Into a retort of 2 litres capacity put 1 kilogramme of oxalic acid, 100 grammes of water, and 1 kilogramme of glycerine; distil at a temperature between 100° and 200°, avoiding a higher temperature; add $\frac{1}{2}$ a litre of water from time to time till 6 or 7 litres have come over. With care this will be found an excellent method, giving the formic acid quite pure, and yielding the theoretical quantity.

Several correspondents in our next.

PHOTOGRAPHY IN PARIS.

THE EXHIBITION.

IN an exhibition of photographs at Paris, we generally expect to see some of the finest specimens of the best men of the time. It is somewhat singular, however, that some of the first Parisian portraitists do not exhibit in the present exposition. The display of pictures is, however, very perfect, and includes some pre-eminently interesting contributions.

The first impression which strikes us on entering the exhibition, is one of gratification on contemplating the position in which photography is placed by the government. Here a very perfect gallery in the *Palais de l'Industrie* is awarded to photography, immediately adjoining, and in connection with, the exposition of works of fine art, which is equivalent to our Royal Academy exhibition. The gallery is spacious, lofty, and well lighted. The photographs are well hung, within eye-range on the walls, and on small transverse screens. All the productions of each artist are placed together, and numbered consecutively. The catalogue is arranged with the names of contributors in alphabetical order, each name forming a distinct heading, with the contributions stated underneath. The ample space and admirable arrangement add much to the comfort of visitors, and, by preventing confusion, aid materially in obtaining a satisfactory examination of the contributions.

At intervals of half an hour M. Lauerie, the Secretary, delivers a brief address, or rather series of addresses, on the most interesting pictures exhibited, proceeding from place to place and pointing out examples of different processes, the details of which are briefly stated, any questions from the audience being courteously answered. Amongst the subjects thus brought under especial attention were the various carbon processes; photolithography and photo-engraving; photography in colours; and, finally, Mr. Robinson's fine composition "Bringing Home the May," which elicits much admiration on all hands. This picture is admirably hung and lighted, and is seen to much greater advantage than it was in the dingy gallery in Sussex Street. As Englishmen, we have much reason to be gratified at the position awarded to this picture, which is without any rival in France, and at the ungrudging admiration it has received amongst French photographers and lovers of art generally.

By far the greater part of the contributions consist of portraiture, the bulk of which is very good. We were glad to observe that a reaction in favour of large portraits seems to have set in. There is a comparatively small display of card portraits, compared with those of larger size. Large busts and half lengths on whole plates, and full length figures on plates 10 by 8 or 12 by 10, largely prevail in the exhibition. Many of these are admirably posed, and are also very fine examples of photography. In the majority of instances these are slightly retouched. It is but fair to add, however, that this retouching appears, in the majority of instances, to result rather from fastidious taste in the artist than from imperfections in the pictures.

Obtrusive lights, arising rather out of the nature of the subject than from imperfect photography, are taken down, sharp crisp touches given here and there. To exhibit a picture without retouches appears to be less a matter of pride than to exhibit a good picture; and if retouching will improve the result it is done without hesitation. Vignette heads, on 5 by 4 plates, were exhibited by several artists. Many of them were very fine, and we fancy with become popular in place of card portraits.

We were glad to perceive that there was but one frame of "postage stamp" portraits, and these were poor. The experiment of introducing this style of portraits has, we understand, proved an entire failure in Paris, the good taste of the inhabitants rejecting such puerilities. We deprecate very much the degradation of the art to the production of mere toys or playthings, which can have no possible artistic value, and which, by decreasing the demand for other portraits, may materially interfere with the commercial results to professional photographers. We apprehend that "postage stamp" portraits will meet with as little favour in this country as in France, unless professional photographers of standing indiscreetly aid in giving them a factitious popularity.

Besides the display of ordinary good photography, there were several essential novelties or processes of peculiar interest illustrated. Amongst these the specimens of photography in natural colours, by M. Niepce de St. Victor, excite much interest. These consist of reproductions from coloured pictures upon silver plates. By means of recent improvements in the process, M. St. Victor is enabled to give them a durability in the light of about twenty-four hours. The Secretary exhibits the specimens for a few moments at each of his half-hourly addresses, and then quickly returns them to the box in which they are kept. The colours are very vivid, especially a fine yellow, of the tint known as Etruscan yellow; the scarlet is also vivid. There are pinks, blues, greens, and some other tints. The general effect of the pictures is similar to that of an un-fixed Daguerreotype, the image being imbedded in a kind of film, something like the unaltered film of iodide of silver on the Daguerreotype plate. The pictures are extremely interesting as demonstrating the possibility of reproducing natural colours by the aid of photography; but they do not at present promise to be of further value.

Amongst carbon prints some of M. Charavet are by far the most perfect we have seen. Some of the portraits exhibited seem to leave little to desire as to delicacy, half-tone, and perfect modelling.

Perhaps the most wonderful application of photography, illustrated in this exhibition, is the invention of M. Willeme, known as photo-sculpture, by which process several fine statuettes exhibited have been produced. By the courteous introduction of M. Lacan, to whose good offices we are indebted for much of our pleasure in Paris, we were enabled to witness the operations in M. Willeme's *atelier*, and shall, on another occasion, give a detailed description of the manipulations.

Nothing in this exhibition interested us more than the contributions, prints and negatives, by M. Blanquart Evrard, intended to demonstrate, as the catalogue states, that by the method recently published by the author (See PHOTOGRAPHIC NEWS, p. 281 and 306) "the photographer can, without the aid of the camera, continue to complete his negative, change the effect, and correct it by means of light." The negative exhibited is of a group of sculptured figures in *bas relief*, apparently from a frieze. These figures, of course, all occupy one plane; but, to show the capabilities of the method proposed, several of the figures have been made much more brilliant and dense, and appear to stand out in much bolder relief than the others. The original negative is soft and grey; but the figures which have received the extra exposure, described by the author, are of much warmer and more non-actinic colour. The method is, we think, well worthy of further attention, as giving great scope for obtaining additional artistic effect in photographs, without the re-touching of the pencil.

Examples of a somewhat amusing modification of the stereoscope to which the inventor, M. Cassaignes, appears to attach great importance, are exhibited. The improvement consists in placing in front of the lenses strips of glass possessing graduated colours. These coloured glasses can, by the aid of a pinion, be moved so as to bring different tints between the eye and the picture, in order to vary the aspect under which the scene depicted is examined. By variations of blue, green, yellow, and red, the effects of sun-rise, and sun-set, mid-day, and moonlight, can be imitated. The method is patented in France and several other countries, but although a pleasing toy is produced, we fear the result will not be commensurate with the expense.

In comparing the photography of Paris with that of London, we are not struck with any superiority in the former over the latter, except in one particular. The best French photographers do not excel in any respect the best English photographers; we are not sure that we saw anything in Paris, which of their kind equalled the whole plate vignettes of Mr. T. R. Williams; but in universality of excellence, Paris takes precedence of London. There are more good photographers, a greater number whose works are uniformly excellent, than there are in our own metropolis. We are now speaking of portraiture; in landscape and some other departments, we have no hesitation in claiming the palm for English photographers. Indeed, we have good reason nationally to be satisfied with our position in the present exhibition. There are not more than half-a-dozen English exhibitors, but the very highest position in several departments is unquestionably occupied by Englishmen. The best landscapes exhibited are by Mr. Maxwell Lyte; the best instantaneous pictures, by Col. Stuart Wortley; the best reproductions by Mr. Bingham; the best composition picture perhaps the best picture of any kind in the exposition, by Mr. Robinson. Nothing can exceed the beauty of some of the instantaneous transparencies of MM. Ferrier and Soulier, but they are produced by English lenses, and some of the instantaneous street scenes on paper by other photographers are not comparable with those of Wilson, England, or Blanchard.

But in every department of portraiture there are fewer bad pictures in the Exhibition than are found amongst the productions of some of our own professional photographers. Some of the first portraitists, as we have observed, do not exhibit. Disderi, of whose establishment we shall have something to say shortly, does not exhibit. Levitzky does not exhibit; but some of his pictures, which were shown to us by M. Lacan, were amongst the finest we have ever seen anywhere.

In our next we shall have something to say on the methods of operating in Paris.

THE DECIMAL SYSTEM OF WEIGHTS AND MEASURES.

PHOTOGRAPHERS are especially concerned in any measure which contemplates reform or revolution in the present sys-

tem, or, rather, no system, of weights and measures. On Wednesday evening week a Bill for introducing the decimal and metric system into this country, was read a second time in the House of Commons. We have no great faith that the measure will pass during the present session of Parliament. Honourable members generally, were very willing to affirm the principle of the Bill, but very many are opposed to the trouble involved in carrying it out. A general impression prevails, however, that it is but a question of time, and that this change must inevitably come. Such being the case, it appears to us to be sheer folly to delay the matter. Mr. Ewart, in proposing the second reading of the Bill, said that to obtain a uniform system of weights and measures had been the dream of the Legislature ever since the passing of the Magna Charta. To attempt to obtain uniformity with the heterogeneous systems in existence would be a most hopeless task. And, as a simple, philosophical, and perfect system already prevails throughout the greater part of Europe, nothing can be more reasonable or convenient than its adoption.

The anomalies which exist are familiar to most persons; but it may, nevertheless, be interesting to place a synoptical view of some of them from the much quoted pamphlet on the subject, by Professor Leone Levi:—

"For measures of length we have the ordinary inch, foot, and yard. In cloth measure we have yards, nails, and ells. There are four different sorts of ells. For nautical purposes we have fathoms, knots, leagues, and geographical miles, differing from the common mile. The fathom of a man-of-war is 6ft.; of a merchant vessel, 5ft.; of a fishing smack, 5ft. We have also the Scotch and Irish mile, and the Scotch and Irish acre. There are several sorts of acres in the United Kingdom, and there are a great variety of roods. We have in almost every trade measures of length specially used in those trades. For the measurement of horses we have the hand; shoemakers use sizes; and we are compelled to adopt gauges where the French use the millimetre. The gauges are entirely arbitrary. The custom of the trade is the only thing which would decide the question in case of dispute. For measures of capacity we have 20 different bushels. We can scarcely tell what the hogshead means. For ale it is 54 gallons; for wine 63. Pipes of wine vary in many ways; each sort of wine seems to claim the privilege of a different sort of pipe. For measures of weight we have about 10 different stones; a stone of wool at Darlington is 18lb., a stone of flax at Downpatrick is 24lb., a stone of flax at Belfast is 16½lb., but it is also at Belfast 24½lb., having in one place two values. The cwt. may mean 100lb., 112lb., or 120lb. If you buy an ounce or a pound of anything, you must inquire if it belongs to Dutch, troy, or avoirdupois weight."

Photographers are very familiar with some of the difficulties which arise out of this confusion. They purchase their materials by avoirdupois weight, the ounce of which only contains 437½ grains; but they prepare their solutions by apothecaries' weight, the ounce of which contains 480 grains. Thus, when a photographer purchases an ounce of nitrate of silver, and makes it, without further weighing, into a 30-grain nitrate bath, he probably adds 16 ounces of water, regarding it as 480 grains, forgetting that he purchases by one standard and works by another. "Why," we were recently asked by a gentleman in Paris, "do you not adopt the system in the News of stating all formulæ in grammes, since that method is becoming so common amongst scientific men?" Our reply was, that we were attempting to introduce it gradually to the notice of our readers, from a conviction that it would shortly be adopted universally. We have frequently of late given extracts from foreign journals, without converting the figures into English denominations; but we have generally met with remonstrance from some of our readers when such figures have appeared.

The metrical and decimal system was introduced into France towards the close of the last century. Some of the ablest mathematicians of the day devoted their attention to the subject, and made the necessary calculations. The system has been found to work admirably in practice, and has since been adopted in Spain, Portugal, Holland, Switzer-

land, Sardinia, Tuscany, Belgium, and various other countries, materially facilitating not only freedom of intercourse between such countries, but effecting an immense saving of time to each of the inhabitants in the simplification of all kinds of accounts.

The introduction of the metrical system is not a necessary concomitant of the decimal system; but it is so perfect in principle and working, and the harmonisation of weights and measures throughout the civilised world is an object so desirable, that we do not think the trouble, confusion, and annoyance which the change will, for a while, doubtless engender, can be compared with the great and lasting advantage to be obtained. The metrical system derives its name from the standard of measures adopted, which is derived not arbitrarily, but from a fixed physical source.

The ten-millionth part of a quarter of the earth's meridian is the unit from which the calculations are made. This unit, or first measure, is called the metre (from the Greek word *μετρον*, measure). It is thirty-nine inches and three hundred and seventy-one-thousandth parts of an inch of our measure (39.371 inches). The metre is divided into ten parts, each of which is called a *decimetre*; and this is again divided into ten parts, each of which is called a *centimetre*.

A cubic decimetre is called a *litre*, and this is taken as the unit of measures of capacity.

A cubic centimetre of distilled water, at its maximum density, that is, at a temperature of 39.5° Fah., is taken as the unit of weights, and is called a *gramme*. All the subdivisions and multiples of these units are by tens, and as will be readily seen, the calculations become simple and easy in the extreme.

Our especial object in bringing it before our readers, now that a measure bearing on the subject is before Parliament, is to urge upon photographers to render themselves familiar with the terms and their value in the new system, and thus prepare themselves for the change which will, we hope, speedily come.

Scientific Gossip.

THE MAGNESIUM LIGHT—PATENTS FOR METHODS OF PROCURING THE METAL.

WE have, on several occasions, drawn attention in these pages to the metal magnesium, and have expressed a hope that some day the metal could be obtained in sufficient quantity, and at a sufficiently low price to render it available for the uses of the photographer. The wonderfully brilliant light which is produced by its combustion, the absolute innocuousness of the evolved products, and the ease with which the light can be obtained at any time, with no more trouble than is required to light a candle, all tend to show that the perfection of artificial photographic light would result from the burning of this metal in a properly arranged lamp. Many attempts have been made, with varying degrees of success, to introduce an artificial light sufficiently powerful to enable photographs to be taken by its means at night, or in dark caverns, where no photography would otherwise be possible; and, in many cases, fair success has been met with. The light evolved by all such pyrotechnic mixtures is, however, very feeble, as compared with sunlight, unless an inordinate amount of material be employed, and, in this case, the fumes evolved are difficult to remove readily from the place where the light is produced, and unless they are perfectly removed their poisonous character makes them very dangerous. The magnesium light would be superior in both these respects. A thin wire simply held between the fingers, can be lit as easily as a piece of paper, and burns like a candle, producing a light which is, according to Bunsen's estimate, only about thirteen times less intense than actual sunlight. No injurious fume is evolved during the combustion. A light white smoke is seen rising from

the metallic flame, but this is nothing but magnesia, and is quite harmless. Moreover, the greater portion of the magnesia remains behind, as a friable solid, retaining somewhat the shape of the original wire.

We believe an arrangement of lamp for the magnesium light has already been devised. A spool of wire is gradually unwound, the end being pushed horizontally into the flame of a spirit lamp, where it ignites and continues to burn as long as it is fed with wire. It is in this feeding that the great difficulty has resided. Although it has long been well known, thanks to the labours of Deville and Caron, that magnesium could be procured even easier and at a less price than aluminium, by a slight and obvious modification of the apparatus used to prepare the latter metal, no one cared about risking the necessary outlay requisite to procure the metal in large quantities, when there was a doubt as to whether there would ever be sufficient demand to make the manufacture pay. Now, however, there appears to be a chance of scientific men procuring magnesium at about one-fourth of the price hitherto charged; and as the sensation which is now rising about this metal will doubtless have the effect of introducing as many improvements and lowering the price in as great a degree as have taken place with aluminium, there is little doubt that it will shortly become all the rage, more especially since in colour, lightness, and other qualities it is really a beautiful metal. Before we treat of the more recent patent for the manufacture of magnesium, let us see what has been done before in the matter. Mr. Sonstadt has just taken out a patent in which he claims an immense number of processes and reactions connected with this manufacture; let us examine how the process stood at the time his specification was taken out, so as to be able to judge whether there is any novelty, and, consequently, any value in the recent patent. In Gmelin's chemistry are given processes for the preparation of the metal by the action of potassium and chloride of magnesium, and many of its properties are correctly given as described many years ago by Bussy. In the *Comptes Rendus* for February 23, 1857, Messrs. Deville and Caron gave a detailed paper on the preparation of magnesium, in which they say that it can be prepared by the process employed for aluminium, which, however, must be slightly modified, as magnesium is lighter than the scoria from which it is produced. A mixture of chloride of magnesium, chloride of sodium, and fluoride of calcium is made, and finely powdered. Sodium, in fragments, is then added and intimately mixed with the chlorides, and the whole is thrown by means of a little iron spatula into a red-hot earthen crucible, which is then closed with its cover. In a short time the reaction takes place. When all noise has ceased the crucible is uncovered and the mixture is stirred with an iron rod until the globules of magnesium are distinctly seen. The crucible is then allowed to cool, and when the saline mass is ready to solidify it is again stirred with the iron rod, which collects the separate lumps of magnesium into one mass. The metal is then distilled in a current of hydrogen and then fused in a flux composed of chloride of magnesium, chloride of sodium, and fluoride of calcium. The latter is added to increase the fusibility of the bath.

Messrs. Deville and Caron still worked at the subject, and more recently gave an improved process for the preparation of the metal, in which they recommend the omission of the alkaline chloride, and only use chloride of magnesium mixed with fluoride of calcium for the reduction by sodium, although they state that good results were also obtained by using a mixture of chlorides of magnesium and sodium. They give improved methods of separating the metal from the flux and for melting and casting it into an ingot. Respecting the properties of magnesium they describe it as a silver white metal melting at about the same temperature as zinc, and like it boiling and distilling at a higher temperature. Like zinc it also takes fire and burns at a temperature a little above its melting point. The density of magnesium is 1.75. In the crude state it is brittle, but by distillation it is

rendered pure. The residue left upon the distillation of impure magnesium is a light, black substance, and the distilled metal is covered with crystals of nitride of magnesium which, however, rapidly decompose water upon exposure to the air. When pure, the metal is very ductile; it tarnishes in the air, but not more quickly than zinc, and the oxidation is never very considerable.

So matters stood until Mr. Sonstadt came into the field. The scientific public had been assiduously prepared for the reception of this gentleman's improvements by paragraphs and rumours of something wonderful shortly coming out in the magnesium line. Lumps of magnesium as big as a man's head were mysteriously talked about as having been seen by somebody who knew a friend of the speaker's, and altogether chemists were prepared to welcome with interest a process for preparing magnesium which should introduce a really novel idea in the manufacture of the earthy metals. Judge then how general was the disappointment when upon the publication of the specification it was seen that, almost buried in a host of details of neither sense nor value, the process was Deville and Caron's original method, slightly modified for the worse by the omission of some of their improvements, and by the preparation of some of the materials in a less convenient manner. The specification is tediously long. The first part consists of a long description of a way Mr. Sonstadt has discovered to purify magnesia from sulphates. The novelty—or want of novelty—of this process will be apparent to all our readers when we say that it consists in precipitating sulphate of magnesia with carbonate of soda and washing the precipitate till free from sulphuric acid. This is converted into chloride, mixed with chloride of sodium and evaporated to dryness. The dried material is then placed in a *platinum crucible* (!) and heated to redness. This mixed chloride is then heated to redness in an iron crucible with sodium, and the magnesium is separated from the slag by washing away the salts and picking out the lumps of metal. These are then fused into one lump under chloride of magnesium. The method of preparing the chloride of magnesium is given, the only novelty consists in using a platinum crucible. The patent concludes by a description of the physical and chemical properties of magnesium, which in many respects are identical with those given by Deville and Caron, whilst in others they are imperfect. We have very carefully studied this specification and we can assure our readers that the only points in it which possess the least approach to novelty are the employment of platinum crucibles in one stage of the operation, and the employment of iron crucibles in another stage. Deville likewise proposes to add fluoride of calcium to his magnesium chloride to facilitate its fluxing, and renders the crude metal perfectly pure by distillation. These improvements are omitted in Mr. Sonstadt's specification.

If such a patent as this can stand for a moment, consisting as it does of scarcely anything but wholesale appropriations of other persons published discoveries, there is little doubt that the patent laws require amendment.

Critical Notices.

ELEMENTS OF PHOTOGRAPHY. By CHARLES HEISCH, F.C.S., Lecturer on Chemistry at the Middlesex Medical College. London: Murray & Heath.

This is one of the least pretentious, but at the same time most thoroughly intelligent and trustworthy, of all the instruction books which have emanated from the press. Mr. Heisch is a very old and experienced philosopher, and a first-rate chemist; he possesses, moreover, the art of communicating the knowledge he has gained in the clear, simple, and forcible language, which is of the highest value in a manual of instruction. The author disclaims the intention of producing anything new; but, nevertheless, old facts and formulas are so rationally stated, as to give them a new value.

The chapter on collodion is a most interesting and valuable one, and we shall take an early opportunity of transferring some extracts from it to our columns. The only point which by intelligent authorities will be considered questionable is the introduction, besides the alkaline processes, of a formula for toning with hyposulphite of gold. This is a subject upon which the author has afortime, we believe, defended his opinion, maintaining that if properly conducted the *sel Dor* toning process gives as much theoretical promise of stability in the prints as any other method. We confess, however, that we should prefer to place in the hands of beginners the alkaline or neutral processes only, as less dangerous than those involving the possible action of sulphur. With this exception we can most cordially recommend the little book.

PHOTOGRAPHIC ILLUSTRATIONS OF THE LADY OF THE LAKE. By THOMAS OGLE. London: Alfred W. Bennett.

MR. BENNETT evidently has great faith in the value of photography as a mode of illustration, and to his enterprise the public is indebted for some of the very best examples of this application of the art. The elegant little volume before us is a novelty in this direction: it consists of a very pretty album containing twenty-four card pictures, illustrating the glorious Scottish landscapes immortalized as the scenes of Scott's "Lady of the Lake." The text is supposed to be in every gentleman's library, and we have here the photographs only, duly numbered and named. Some of the photographs are very excellent indeed, and the whole is got up in a very creditable manner.

THE WYE: ITS ABBEYS AND CASTLES. By WILLIAM and MARY HOWITT. The Photographic Illustrations by BEDFORD and SEDGFIELD. London: Alfred W. Bennett.

The text of this little work is extracted from the well-known volume by William and Mary Howitt, "The Ruined Abbeys and Castles of Great Britain." There are half a dozen excellent photographs—four by Bedford and two by Sedgfield—of scenes which have become almost the property of photography—Chepstow Castle, Tintern Abbey, Raglan Castle, Goodrich Castle, the Wye, &c. The volume will form a most elegant gift-book, and we heartily recommend it.

THE PRINCIPLES AND PRACTICE OF PHOTOGRAPHY FAMILIARLY EXPLAINED. By C. JABEZ HUGHES. Fifth Edition, considerably enlarged. London: Published by the Author.

MR. HUGHES' manual after rapidly running through four editions, has in the fifth, doubled its original size. From a simple manual of instruction, it has grown into one of the most complete text books yet published. We need not repeat here all we have before said as to the excellence of the style, and the value of the information it originally possessed; but we must refer to the added matter of the present edition. The work is now divided into three parts: the first consists of instructions for the beginner, comprising all kinds of elementary information. The second part consists of a very complete synopsis of all the dry processes which have had their claims approved by the production of good results. The third part consists of a vast mass of all kinds of information relating to almost every branch of photographic practice. This chapter is a perfect *omnium gatherum*. The author gives not only his own experience, but also hints from almost every one of ability who has written upon the art, with the source of each hint duly acknowledged. Thus in the Chapter on Cleaning Plates, we have no less than eight recipes for plate cleaning solutions, each verified by the

name of its author. We have similar chapters on Intensifying, on Copying, on Enlarging, on Instantaneous Photography, on Transparencies, on Recovery of Gold and Silver from Residues, on Colouring Pictures, on Printing, Toning, &c., and on a host of other interesting topics. The work, unless we are mistaken in our estimate of it, will very shortly be a text book of daily reference in the hands of every photographer, professional and amateur. Our space does not permit us to make extracts in the present number, but we hope to do so on another occasion.

BALLOON PHOTOGRAPHY.

Mr. GLAISHER recently made another scientific balloon ascent, and was on this occasion supplied with dry plates prepared by Dr. Hill Norris; but, unfortunately, no opportunity occurred of exposing them. We subjoin a few extracts from his account of the ascent, which took place on the 3rd ult. from Wolverton:—

We left the earth at 1h. 3m. p.m.; at 1h. 7m. we were at the height of 2,000ft.; at 1h. 15m. we passed above 8,000ft.; a height of 10,000ft. was reached at 1h. 17m.; in nine minutes afterwards we were 15,000ft. from the earth, and rose gradually to about four miles and a quarter at 1h. 55m. On descending at 2h. 8m. we were 20,000ft. from the earth; at 2h. 13m. above 15,000ft.; at 2h. 17m., 10,000ft.; at 2h. 22m., 5,000ft.; and on the ground at 2h. 28m.

Before starting, the temperature of the air was 66°; it decreased rapidly on leaving the earth; was 54° at 3,000 feet high; 49° at 4,000 feet; 41° at one mile; 30° at two miles; and, up to this time, every succeeding reading was less than the preceding, but here the decrease was checked, and while passing from two to three miles the temperature at first increased to 32°, then decreased to 29°. A second increase followed, and at the height of three miles and a quarter the temperature was 35°. A rapid decrease then set in, and at three miles and a half the temperature was 22°. From this time till the height of four miles was reached the temperature varied frequently between 22° and 18°, and at the height of four miles and a quarter the lowest temperature took place—viz., 17°. On descending, the temperature increased to 26°, at the height of 23,000 feet, and then to 32° at the height of four miles. It then decreased 9° in one minute, to 23°. It continued at this value for some time; then increased slowly to 29°, at 19,000 feet, and continued almost constant for a space of 2,000 feet; then increased to 32° at 15,000 feet; and was 32° or 33°, almost without variation, during the snow storm, which we experienced from 13,500 feet to 10,000 feet high, when an increase set in. At 5,000 feet the temperature was 41°, and 66° on the ground.

We reached some clouds at 1h. 9m.; at 1h. 16m. we saw a very faint sun, and expected, as usual, its brilliancy would increase, and that we should soon break into clear sky. At the highest point reached, about $4\frac{1}{2}$ miles, the sky was very much covered with cirrus clouds; the sky as seen between them was of a very faint blue; as seen from below through a moist atmosphere we were above clouds, but there were no fine views or forms, all was confused and dirty-looking, no bright shining surfaces, or anything picturesque, and the view was exceedingly limited, owing to the thick and murky atmosphere.

At 2h. 3m. on descending we lost even the faint sun, and re-entered fog, and experienced a decline of temperature of 9° in little more than a minute. At 2h. 6m. there were faint gleams of light, fog was both above and below, but not near us. At 2h. 7m. large drops of water fell from the balloon, covering my note-book; the next minute we were enveloped in fog, which became very thin at 2h. 14m. At 2h. 14 $\frac{1}{2}$ m. rain fell pattering on the balloon; this was shortly succeeded by snow, and for a space of nearly 4,000 feet we passed through a snow storm; there were many spiculae, and cross spiculae, with snow crystals small in size, but distinct; there were few, if any, flakes, as we descended the snow seemed to rise above us.

I took up Herschel's actinometer, and once only, at four miles high, the sun shone on it, during which time the reading increased nine divisions only in one minute, while on the ground Dr. Lee and myself, at eleven o'clock in the morning, had determined the increase of thirty-three divisions in one minute.

This instrument I hope to be able to use at great heights on future occasions. At the height of three miles a train was heard, and at a height exceeding four miles another train was heard. Those heights are the greatest at which we ever heard sounds, and indicate the generally moist state of the atmosphere. Before quite reaching the highest point I examined portions of the blue sky with a small spectroscope, kindly procured for me from Paris by Mr. Simms, which I could readily use anywhere, and the spectrum was seen just as from the earth under the same circumstances. I could not use the large spectroscope at all throughout the journey, and through the thick atmosphere and large amount of vapour I was unable to make any use of the camera kindly prepared by Mr. Melluish, with plates specially prepared by Dr. H. Norris, of Birmingham. This ascent must rank among the most extraordinary ever made; the results were most unexpected. We met with at least three distinct layers of clouds in ascending, of different thicknesses, reaching up to four miles high; when here the atmosphere, instead of being bright and clear, as it has always been in preceding ascents, was thick and misty, but perhaps the most extraordinary and unexpected result in the month of June was meeting with snow and crystals of ice floating in the atmosphere at the height of three miles, and of nearly one mile in thickness.

Mr. Negretti has received a large number of suggestions for overcoming the difficulties he encountered in his attempts at balloon photography. He writes to the *Daily Telegraph* on the subject, as follows:—

Allow me through the medium of your journal to answer *en masse* the numerous correspondents who have honoured me with their counsels and suggestions, with reference to my late balloon experiments, and to apologise to them for not answering them individually. I would begin by way of a general reply to remind them that:—1st. The car of a balloon is of limited size. 2nd. That the car is for the best of all reasons made of flexible materials, *i.e.*, wicker work. 3rd. That the balloon will only carry a limited weight. 4th. That the balloon, itself, is made of a light textile fabric; and 5th, that the balloon goes with the wind and not through it, in fact, just as a barge drifts with the tide. Now, having considered these points, it will be evident that a stiff sail and boom could not be attached to a soft flexible balloon, as suggested by one gentleman; nor, as hinted by another, could a rudder from the car be conveniently used, from the fact that the necessary gear would take up more space in the car than I could spare; and even if its adoption were practicable I feel confident it would not be of any use for the reasons stated above. Moreover, I believe the overhanging rudder would tend greatly to make the balloon more unsteady. There is a plan that seems to have found general favour with my advisers, and has been suggested as likely to get me over my difficulties with reference to the rotatory motion of the balloon; the remedy for this annoyance is that I should use a gyroscope as a stand for my camera. Now, sir, there is no one who admires that beautiful instrument more than I do, and there is no question that by employing a gyroscope I should obtain all the steadiness that I require for my pictures. Mr. Piazza Smyth, the Astronomer Royal for Scotland, made use of a gyroscope on board the late Mr. R. Stephenson's yacht, for taking astronomical observations at sea. This was whilst on his passage to Tenerife, but Mr. Piazza Smyth had the deck of the *Titania* on which to place his gyroscope, and a crew of sturdy sailors to set it in motion, and not the circumscribed space of a balloon car.

I am afraid that the gentlemen who kindly suggested the gyroscope have not given the subject their serious consideration. My opinion is, that, supposing no ropes or ring were in the way, which absolutely prevents an apparatus of the kind being used, a gyroscope and spinning gear that would support and keep steady, in any position, the camera and lenses required, would weigh several hundredweights, and would take the united exertions of three or four persons to set it in motion. I need not say that I never could hope to adopt this plan. No, Sir; if photography is to be done from a balloon, the photographer must mainly depend on having suitable and appropriate apparatus for keeping his camera freely and steadily balanced, on skill in manipulation, the rapidity with which he can expose the sensitive plate, and judgment in seizing the right moment for exposure, for there are moments when there is only a progressive movement, which, if towards or leaving an object even

at the rate of 15 or 20 miles an hour, every photographer knows we care very little about.

Messes Nadar and Goddard did, in 1858, try to take photographs from a balloon fastened to the ground with ropes, but even with the balloon in this captive state, they did not succeed in obtaining sufficient steadiness for their purpose. Photography has made wonderful progress since that, and, for all that, is still in its infancy. Up to the present time I believe I am the first person who has ever taken a photograph from a free balloon. What now seems a difficult matter will be eventually a very simple affair, and in my present task I am only attempting to forestall the regular course of events.

Mr. Negretti here overlooks the fact that some successful experiments in photography from a balloon have been made in the United States. In the year 1860 Mr. Black ascended from Boston, and exposed six plates. Of these two were stated to have been very successful. The results were shown to the American Photographic Society, and described as clear and sharply defined, giving a view very similar to that seen by the aeronauts. What methods were employed to overcome the difficulties in the way, we do not remember. The object of the ascent was, if we remember rightly, to ascertain how far the operation could be made useful in military reconnaissance.

THE ÆSTHETICS OF PORTRAITURE.

BY R. DISDERI.*

Nothing in photography appears easier at first sight than a portrait. It seems sufficient, to ensure the desired result, that the model should remain perfectly still, and that the operator employ the shortest possible method. Does not the light copy the object with perfect accuracy, and give a faithful *fac-simile*? How is it, however, that so many portraits are not at all good likenesses, and that it is so rare that the resemblance is so complete as to satisfy the friends and the relations of the individual who has been the model? How is it that the different representations of the same person are so varied that they sometimes express very different, and sometimes even opposite characters? Are there not amongst the same portraits those which may be considered as good likenesses, some equally pleasing and others ugly? What is then the meaning of this difference in the copies of one and the same object, if it be not that this object presents infinitely varied aspects, amongst which only a small number are capable of giving an exact and pleasing representation of its true character, which alone constitutes the portrait? In truth, to make a portrait it is not necessary to reproduce that proportion or form of the individual with mathematic exactitude; but it is requisite, above all, to represent them according to the character of the individual, with the modifications and developments which have been given to him by habit, opinion, or social life. Those who know the individual to be represented will come to a very clear understanding on this point which is the result of all the various aspects in which they have seen him; if they knew how to express this idea, they would render the portrait truly resembling. The artist must see and comprehend his model in the same way. In addition to this, he must attempt the beautiful without losing anything of the truth.

Neither the photographers nor their models are impressed with this idea. They prefer to think that the resemblance consists in the exact reproduction of the proportions, the features, and the attire. Thus portraits are very often caricatures of individuals, representing only the unpleasant traits of the original, with something of his features by which he may easily be recognised. In such photographs the details are the most admired. One recognises the beard, the dress, the various peculiarities of the individual that are even more insignificant than those we have just mentioned; and sometimes we may notice a familiar smile, and this but very rarely. But where is the moral character that we ad-

pire so in the person represented? his serious or lively expression? his good disposition, that charms us? The orator, for instance; do you recognise him as the individual that impressed your mind so forcibly by his splendid flow of eloquence? Is it in this attitude that the general stood before the columns of his enthusiastic followers? No, they would scarcely recognise their leader in this unnatural position, if it were not for his uniform, and some unmistakable peculiarity of form or feature.

The first step that a photographer should take to obtain a good portrait, is to penetrate the numberless aspects under which he sees his model, and to ascertain the real type and character of the individual. It is thus alone that he is enabled to conceive an appropriate representation, and to choose the particular attitude and expression, as well as the distance, light, and accessories of the picture; and knowing these, he seeks to obtain the optical combinations requisite to express the result of his observations; in a word, he composes his portrait.

To compose a portrait is, therefore, to choose the best mode of representation, and to combine all the parts in view after this unique method. We will endeavour to explain this clearly by the following example:—Imagine a philosopher, who has passed his life in study and tedious research. The habit of constant meditation has marked his forehead, which rests on his hands, with deep vertical furrows; he is a man below the ordinary stature; his mind seems to have been developed at the expense of his body; he is calm and benevolent; his smile full of sagacity. These are the characteristics of his appearance in every-day life, when he is surrounded by friends and relations; his attire is naturally in keeping with his moral and physical being. It is very simple, and evidently a matter of very secondary importance with the wearer. Such is the man who desires his portrait. He will probably present himself to you in a costume for the occasion, which in no respect resembles his ordinary apparel. He will put himself in a stiff premeditated position, holding a large folio in his hand; but, preoccupied with his studied expression, he does not, in reality, read a single line. It is for the photographer to distinguish, under these borrowed expressions, the true and genuine character of his model.

Has he once made himself master of the personality of his subject, he will easily conceive the style in which he ought to be represented. The aspect of the portrait ought to awaken, independently of resemblance and the like considerations calm and serious ideas; it must possess simple attitudes, an interior light distributed in tranquil masses, with half shades, deep background, and a great sobriety of accessories. The head, being the seat of thought, presents a brilliant and luminous aspect. Such is the style to be adopted in this case; any other would be unlike and inappropriate, and would not produce the profound and powerful resemblance that we desire.

We must now proceed to combine the details and parts of our picture; but as it is the knowledge of the individual which has served to determine the style, all the details must be in precise agreement and harmony with it. If the photographer is efficient in the other principles of his art, he must thus obtain both a striking unity and a large and beautiful resemblance. Let us take another example, in a type of totally different character, namely,—a soldier, although very young, he has acquired the right to command; his carriage, looks, his entire bearing, express pride and courage; he has distinguished himself in the late war by acts of unusual daring.

The aspect of the picture is clearly indicated; life, passion, and energy must here be expressed. It would be absurd to wish to treat this portrait after the same method as the former one. The open air, plenty of light, no mysterious half tones, the body firmly posed, the gesture frank, without anything vague or uncertain,—numerous details, so scattered as to confuse the beholder; such would be the proper mode of treatment of the subject we have just described.

* From the "Æsthetics of Photography," in the "Universal Text Book of Photography."

We do not pretend to say that whenever we have to take the portrait of a learned man, or a soldier, it would be necessary to follow one of the styles that we have just indicated; on the contrary, we merely indicate the general character, leaving it to the reader to modify the aspect given to the picture, by as many differences as he finds in the individuals themselves. The severity of thought in the sage is tempered by enjoyment. The ardour and energy of the soldier is often accompanied by benevolence, and even tenderness. These different shades and degrees must, of course, be clearly expressed in the likeness.

That which strikes us first, in the individual, is his structure,—the width of his body in proportion to the height. It is necessary to take a sufficient distance, so that the difference of the planes and surfaces cannot interfere with these proportions. If the object be sitting with his knees and feet turned towards the lens, the head will be found to be on a level, upwards of a foot distant from that of the knees. This deformation would give the idea of a small head, a feeble body, and strong legs. The operator is, of course, always obliged, by the necessity of obtaining clearness in the field of his image, to take a sufficient distance. However, the distinctness of all the parts does not always indicate that the proportions are preserved. The perspective effect exists, but although correct in itself, it gives incorrect appearances to the reality. Thus, the artist would allow a considerable distance, if he wishes to preserve the exact proportions of his model; but, as his aim is not only to produce a correct, but also a beautiful representation, he will attempt, by varying the distance, to modify and embellish his model, without altering its character. If he wishes to take a good portrait of a person who has slender legs and a large head, he could shorten the distance a little, so as to diminish their ugliness, and give them a better proportion. Of course, the artist dare not do too much in this sense, for, unless he seizes the exact moment when the modification must not be continued, he will spoil the resemblance. What we say here with respect to the general proportions, is applicable to all parts of the figure. The disposition of the abridgments, in comparison to the distance, allows the artist to preserve the general character of the stature of the individual, and, at the same time, to improve it. It is impossible to foresee all the circumstances—but it is sufficient to explain these different optical effects to the photographer, for him to understand why so many portraits, in which the perspective is irreproachable, give the idea of individuals being little, or tall, although the originals do not in the least possess these proportions.

The position of the personage in the frame, and the disposition of the accessories, are also practical means of determining the stature of the individual, which the photographer should by no means neglect. Thus, the figure will appear much larger, if the head is placed near the top of the frame and plenty of free space left at each side. It will be increased and diminished in size as it is approached to the right and left edge of the frame, with a good deal of space above it. We shall, therefore, be liable to diminish the resemblance of a portrait considerably, by not paying sufficient attention to these effects, and deprive ourselves at the same time of modifying and embellishing, to a certain extent, the proportions of the model.

The choice and disposition of dress have a great influence on the proportions; and close fitting light cloth garments increase the dimensions of the head, the hands, and the extremities; a flowing and ample dress, on the contrary, renders these parts little and delicate.

Again, by the direction of the light, and the distribution of the lights and shades, the artist is also able to increase the character of the proportions which constitute the resemblance of the individual, giving, at the same time, a new beauty to the likeness; he will render certain parts thinner by plunging them into the half tone, or by burying the outline in the shade; he will deepen and augment other proportion, by surrounding them with light. Thus, he would

increase the size of a head that appears too small, by throwing the light on the face; and diminish the size by choosing a tint that would throw one half of the face into the shade. In general, a dark background serves to make heads appear small, and a light one increases the size. Backgrounds of a middle tone, on which the lights and shades are equally developed, are the best qualified to give an idea of the exact dimensions.

It is by all these means, combined, that the image obtained presents this first and so important an aspect, resulting from the stature of the model, and which causes it to be recognized at the first glance by the masses that it offers to the eye, and quite independently of all detail, or peculiarity of feature or dress. It is also by these means that the artist is able to embellish the proportions, without passing the limit of resemblance.

A question which seems to attach itself, naturally, to the one we have just treated, is that of the real size to be adopted for the photographic portrait. Without doubt, the importance of the subject ought to serve as a guide. It would scarcely be proper to give the same dimensions to the portrait of a celebrity, as to that of a little girl playing with her doll. However, the difference ought, above all, to depend on the mode of treatment of the picture, and on the disposition of the scene, which the character given to the subject presents. It is in the importance of the aspect, and in the gravity of the lines, that the artist ought to seek the character, and not in the dimensions. The Greeks and the Egyptians have expressed the majesty of their gods and heroes, in bronze, or clay images, even less than an inch in length. The photographer, in the question of real dimension, must, above all, consider the destination of his picture. If it is to be placed in a very open position, he will increase it in size to that of life, or even beyond. If, on the contrary, the portrait is destined to adorn an ordinary apartment, or a boudoir, he will make it of much smaller dimensions. Should it, however, be destined for a brooch or locket, the likeness must possess æsthetic beauty and majesty, provided the subject will admit of so elevated a style. We scarcely need add, that the methods of augmenting the size render all dimensions possible to the operator, whatever the reduction may be that the original image has undergone, on account of the choice of distance.

The portrait may represent the individual either in full length, in half size, or merely the bust; portraits are even taken with the head alone; lastly, one may group several persons in the same portrait. It is evident that the artist should, by no means, be governed by chance; and that here as well, the rules of the art must guide him in his choice.

The full length portrait is the most suitable of any to express the complete resemblance of the individual, from the expression of the physiognomy down to fine attitude and proportion; but what difficulties the artist has to overcome, before he is able to take a perfect likeness, with regard to resemblance and beauty!

In the full length portrait, we are not to be guided only by the inflexions of the neck or the arrangement of the arms; it is the play of the muscles and sinews that determines the general situation of the other parts of the body; the visible position of the feet does not hide, from the eye of a beholder, the absence of equilibrium in the movement. However excellent the inclination of the head, or the disposition of the shoulders and arms may be, if you make the slightest fault by giving an unlucky turn to the knee, or by placing the foot in a bad position, you destroy the whole logic of the position. Nothing is easier in such a portrait than to fall into awkwardness, without resemblance, or even into ugliness. It is, of course, apparent that the difficulty must be increased by the necessity of producing a resemblance.

The half size, or half figure portrait, ought to give a nearly perfect idea of the individual; it shows the attitude of the body, and indicates the position of the lower extremities, which are absent. If the model is standing erect, the frame will pass about the middle of the thigh; if the model is

sitting, the knee and part of the leg will be visible. If this be not so, the pose would be bad, and present to the eye an unpleasant incompleteness; for the same reason, the hands and arms should be full in view.

In the bust portrait, the person is represented as far as the chest, without either the hands or the arms. In this case, the head is everything, and the bust is merely represented to sustain it, and give it its true size and proportion. If the bust be too large, the eye of the spectator naturally desires the arms, hands, &c. One must, however, be very careful not to fall into the opposite excess, by giving too little of the bust, as the head would appear quite out of its proper proportion; the nature of the model is the surest guide as to the importance to be given to the bust. The modifications that you can obtain, by means of contrast, are important aids for obtaining resemblance and increasing beauty.

It follows, from what we have just seen, that the head should never be represented without the bust. The effect of such a portrait is altogether devoid of correctness and unity, and does not offer a single point of comparison by which the spectator could judge of the proportions of the head with respect to the rest of the body; a matter of much importance, as this is one of the most striking characteristics of the individual.

(To be continued.)

STEREOSCOPIC MANIPULATIONS IN THE FIELD.*

THE plates which I use for the reception of the stereographic negative are seven inches long by three inches and a half wide. By having the plates somewhat larger than absolutely required, allowance is thus made for any defect that might be visible on the ends or edges, which are more liable to such than the central parts; for if it should happen that the glass corners of the plateholder have not been thoroughly cleaned before the insertion of the sensitized plate, or that the silver solution has not been allowed to drip off after it has been withdrawn from the bath, the fluids in the corners (especially if these are cemented and not wholly of glass) becomes readily decomposed by the lac or resin with which the pieces are cemented, and by capillary attraction arises along either end, and moves on the lower horizontal edge, and produces a reduction of the silver in these parts, as if the film were marbled.

Such an occurrence is very troublesome, and ought to be avoided, and can be avoided in general as follows:—

Clean the glass corners thoroughly every time before the introduction of a new plate; allow all extraneous silver solution to run off into the bath before the plate is entirely removed from it; finally, with a piece of blotting paper or an old rag, carefully remove all fluid from the posterior surface of the plate and corners. In the last operation it requires great caution lest any part of the protuberant portions of the blotting paper or rag should, by the quick motion, lap round the edges, and thus disturb the collodion film. As soon as all extraneous silver solution has thus been removed (and, of course, all these operations have to be performed in darkness), it is placed in the plateholder and inserted in the camera.

I need scarcely remark here that the interior of the camera must be quite dark; in field-work, that is, outdoor-work, a mere pin-hole would allow sufficient light to penetrate so as to destroy the best negative by fogging the whole surface; and not only must the interior be quite free from the ingress of light, but all the parietes must be stained or coloured of a dead black, as also the inner surface of the tubes containing the lenses. The greatest care, in like manner, is required in drawing out the slide and again in replacing it, after the collodion film has been impressed with the image, in order to exclude every ray of diffused light. It is well, therefore, to throw over the upper surface of the camera a large black cloth, so that, in drawing out the slide, the amateur seizes it together with the cloth, and draws both up or sideways at the same time. The focussing cloth, as an auxiliary in this respect, is left on the posterior end of the

camera to keep out all light that might penetrate through any crevice in the grooves in which the plateholder slides. By never omitting such cautious manipulations, many an inconvenience and unexpected disaster will be avoided, which are frequently attributed to the collodion, the bath, or the developer.

Another caution in landscape photography or stereography is to avoid exposing the plate too long; if the lenses be good ones, that is, well corrected aplanatically and achromatically, four or five seconds, for a lenticular aperture of an inch and a half and a diaphragmatic opening between the lenses of half an inch, will be found, in general, sufficiently long, and frequently much too long. Stereographic negatives in the field seldom require more than two seconds with such a stop; in fact, sometimes when the weather is very fine, the air quite clear and totally free from any haze, a quarter of a second will produce a very respectable negative. Let the circumstances be as just described, and let a plate be exposed for thirty seconds; a picture will probably be produced that might mislead the beginner and induce him to lengthen the time. On the contrary, let the student begin with one second; if the picture comes out quite distinctly in all its parts, with a proper contrast between the lights and shades, and containing, besides, the middle tints, the time, probably, will be quite sufficient, especially if the negative has to be intensified afterwards. Where the proper opacity is to be developed by the first operation, a longer time is required. In this case a very weak developer must be used, otherwise the development will be quite unmanageable; as soon as the slightest appearance of fogging in the high lights becomes visible, the plate must be instantaneously washed. By shortening the time, the operation of development is entirely within the control of the artist; and the intensification afterwards can equally easily be regulated. The process of intensifying can be performed either immediately, that is, before the plate is dry or any time afterwards. It seems to me to be a good practice to perform this operation after the labour of outdoor work, at a time when there is no hurry, and where there is every convenience. For such purposes the edges of the negatives have to be varnished by running the side of a glass rod, dipped in varnish, all the way round so that the collodion film becomes covered in width of one-tenth of an inch with this glutinous and protecting substance. The varnish is then allowed to dry spontaneously. So treated, the plates can be hoarded away and strengthened at any convenient opportunity. Supposing the day and moment have arrived when the negatives have to be intensified. The plates are immersed in soft water and kept there for at least half an hour; in this time the film has become softened and impregnated with water, and is thus rendered suitable for the action of the intensifier.

INTENSIFYING PROCESS.

It is supposed that the negatives are suitable for intensifying and have been thoroughly washed, and, if dry, thoroughly soaked. If there be no middle or intermediate shades in the given negatives it cannot be expected that the intensifier will produce that which already has no existence. The office of the intensifier is to *thicken and darken* the shades and half shades that have already appeared under the developer, but not to produce shade and half shade. The process, therefore, is twofold, consisting in *thickening* the existing deposit, and then in *darkening* the thickened deposit.

TO THICKEN THE ACTINO-SILVER DEPOSIT ON THE COLLODION FILM.

The shades receive a deposit, as it were by galvanic action, in various ways. In the first place, if we pour on the wet surface of the negative a solution of bichloride of mercury quickly, so that the action can commence simultaneously in every part of the negative, it will be found that the shades increase in opacity and become more and more dense.

Secondly, throw the plate with a dilute solution of the red iodide of mercury dissolved in iodide of potassium until the same result is obtained. (Iodide of mercury can be bought, or prepared as follows:—Drop a solution of iodide of potassium into one of bichloride of mercury as long as a red precipitate is obtained; as soon as this precipitate has subsided, pour off the supernatant liquid, wash well and several times with water, and again pour off all the liquid above it. Now drop upon the precipitate a saturated solution of iodide of potassium until the red-coloured substance is entirely dissolved, and the solution

* *Humphrey's Journal.*

† Silver-wire corners are almost universally used in this country, which prevent the trouble referred to.

has become transparent. This is the solution in question, which can be diluted *ad libitum*.

Thirdly, the plate may be flowed with tincture of iodine, or a solution of iodine in iodide of potassium, until the shadows become slightly and uniformly yellow and opaque. In addition to these method others might be enumerated.

TO DARKEN THE THICKENED DEPOSIT.

The film, thickened with bichloride of mercury can be darkened with either ammonia, sulphide of potassium, sulphide of ammonium, pyrogallic acid and nitrate of silver, &c.

The other films can be rendered dark-coloured by flowing the plates with either pyrogallic acid and nitrate of silver, the protosulphate of iron and nitrate of silver, or with an alkaline sulphide.

It is not absolutely necessary that the shadows should be black in order to produce a good negative; the thickened film produced after development either by a solution of protosulphate of iron and a few drops of nitrate of silver, or by that of tincture of iodine, or solution of iodine in iodide of potassium is quite as efficacious in producing a good print, whether blackened or not, the film being of that spectral colour which is as impermeable to light as black.

It is difficult to say which mode is the best; each operator has his favourite method; and I prefer intensifying with pyrogallic acid and nitrate of silver, first thickening, where I think it is necessary, with a solution of iodine in iodide of potassium. In all cases of intensifying it is to be recommended that the solutions be dilute, otherwise the deposit will be quite granular, and will render the negative unfit for printing by the production of pictures covered, as it were, with the small-pox. A soft and uniform deposit can be obtained only by dilute thickening and intensifying agents.

Supposing the stereoscopic negative is sufficiently intense, and in other respects perfect, it is dried and varnished, and again dried. By means of a diamond, it may now be cut in two in the middle. From either half, reckoning from the middle, a portion or slip is cut of two inches and a half in width. These two slips, which contain the right and the left side picture, are placed upon a piece of glass five inches long and four inches wide, in such a manner that the left slip is placed on the right side and *vice versa*. The two slips are held in their place, and in contact in the middle, by means of gummed narrow tape along the upper and lower edges and the projecting edges of the underlaid glass. Prints taken from a negative so arranged require no transposition, which they always do if printed from an uncut negative.

A SIMPLE METHOD OF TRANSFERRING THE COLLODION NEGATIVE FILM UPON PAPER.

BY DR. SCHNAUSS.

THE chief fault in the collodion process is the fragility of the glass. Many beautiful glass positives have thus been destroyed; and this may have probably led to the invention of the Pantotype process. Unfortunately no substitute has yet been introduced for glass negatives, although there has been no want of propositions in this direction. Such a substitute is quite a desideratum; for the great pressure in the printing frames is continually exposing the negative to fracture, especially if plate glass is not always used for the reception of the collodion film. Besides this, to the tourist a large quantity of glass plates is quite a burden. To obviate this inconvenience I have for some time been instituting a course of experiments, in order to find means of transferring, by a simple and trustworthy method, the negative collodion film to paper. These collodion paper-negatives naturally can be preserved and transported much more conveniently than glass negatives, and yield, whether waxed or unwaxed, sharp and intense prints. If the papers are not to be waxed (and this is not at all necessary with fine paper), this circumstance has to be taken into consideration during the intensifying of the negative, so as not to carry it too far; for the opacity of the shades is much increased by the paper.

The preparation of the paper is simply as follows:—A half or a whole sheet of paper is pinned smoothly upon a horizontal board, and smeared as uniformly as possible with a hot solution of pure gelatine of so strong a consistency as to congeal when cold into a firm film. It is better not to cut the paper into too

large size, but rather into pieces suitable for the different sized glasses used, because of the facility of covering the surfaces more uniformly with gelatine than when whole sheets are employed. Finally, the boards with the gelatinized papers upon them are reared perpendicularly to dry. All creasing of the paper must, as far as possible, be avoided, because the gelatine collects more abundantly in the creases. As soon as the sheets are dry, they are placed in a portfolio and subjected to a slight pressure, in order to preserve them as smooth as possible.

The method of transferring in question I have as yet practised with collodion films whilst they were still wet, and proceed as follows:—

I use a good negative collodion of about the consistency of the ordinary transfer-collodion in the Pantotype process. As soon as the picture appears, by means of the iron developer, sufficiently intense for the purpose, although still too weak for direct printing, no further intensifying is required with pyrogallic acid. The latter expedient is required only when the solutions are newly made, which, it is well known, do not yield intense negatives. After a few experiments it is easy to determine the degree of intensity most suitable for the purpose. In all cases the picture must exhibit middle tones and be free from all fogginess.

This method is best adapted for transferring portraits where the heads are not over small, on quarter, half, or whole plates, as well as landscapes and architectural pictures on whole-sized plates or larger.

As soon as the picture is fixed, it is well washed and afterwards flowed with the following solution:—

Hydrochloric acid	1 drachm
Alcohol	1 "
Water	2½ ounces.

Which is kept in motion on the surface for a few minutes. The negative is then again well washed. In the meanwhile a piece of the gelatine paper, of a size somewhat smaller than the glass, has been placed upon water with the gelatine side downwards, taking care of course to avoid bubbles. In winter lukewarm water may be used.

The glass negative is now placed on the table, with its collodion side upwards and still quite wet; upon this surface the gelatine paper is removed from the water, allowed to drip for a moment, and then carefully placed, gelatine side downwards, on the collodion film so as to avoid all bubbles of air between. The requisite manipulation for this purpose is known to every photographer, being similar to that required in the transference of positive pictures.

As soon as the protruding edges of the collodion film have been folded back upon the paper, the whole is reared on one end for a few minutes, so as to allow the fluid to flow off from between the collodion and gelatine films; after this it is placed in a printing-frame with a few folds of blotting paper on the back, and submitted to gentle pressure, but only for a few minutes, otherwise the picture would dry, and then it would be impossible to remove it from the glass. Hereupon the gelatine paper is raised at one corner to see whether the film adheres to it. If this be the case, a few drops of water are allowed to fall between the glass and the film, and the glass is held obliquely and in such a direction that the water can flow where the film rises from the glass. If the operation is successfully performed, the transferred picture is hung up to dry.

Where the papers are required to be waxed, they are placed with the collodion side downwards on a warm copper plate, and then carefully smeared with a mixture of wax and hart's tallow. It is finally pressed, whilst still warm, between the folds of fine bibulous paper, in order to remove all the superfluous wax. The wax-mixture is best prepared according to Martin's recipe by melting together three parts of white wax and two parts of purified hart's tallow. After the mixture has been intimately stirred together, it is poured into a cylinder of cardboard closed at the lower extremity with a cork. When cold it can be removed from the mould like a candle without a wick, with which the warmed paper negative can be smeared by a gentle pressure.

By this process very good and satisfactory results can be obtained, of which fact those who attend my course of instruction have often had an opportunity of convincing themselves. The prints are just as fine as those from glass negatives, especially if the paper has been waxed. To no indeed they appear to possess an advantage over the latter owing to a peculiar softness with which they are endowed.—*Photographisches Archiv*.

Proceedings of Societies.

THE AMERICAN PHOTOGRAPHICAL SOCIETY. FORTY-NINTH MEETING.

THE Society held its regular meeting for June, on Monday, 8th inst., at the University; Professor JOY in the chair; Mr. N. G. BURGESS was appointed secretary *pro tem*.

The minutes of the last meeting were read and approved.

A letter was received from the president, enclosing a communication from Mr. John Johnson, of Saco, Maine, on the growth of plants under different coloured glasses, and giving the result of some experiments.

Method of Preserving Negatives, including Varnishing.—This being the special subject for the evening.

Mr. HULL inquired what was meant by preserving negatives?

Mr. BURGESS: I understand to keep them from becoming useless, which they will, if not preserved. Sometimes we preserve them by varnishing, sometimes with gum arabic; they can be preserved by mica, or in half a dozen ways.

Mr. CRUM: Perhaps there is not a subject fraught with more interest to photographers than this. As every practical photographer knows, negatives are the subject of a good deal of trouble and anxiety. We are told the best way to preserve them is to put them in grooves, after being finished, lay them away, keep them from the dust, &c. But, we have found, by using various varnishes that the negative will depreciate, and lose not only vividness and transparency, but intensity. Some varnishes, instead of being a benefit to negatives, are a curse, because they become freckled and streaked. The cause, I am unable to determine. The plan I adopt in my process is to dry them as soon as convenient, and varnish them immediately.

Mr. BURGESS concurred that this was one of the most vexatious matters connected with the art. Frequently they wanted to preserve negatives more than a year after being taken. If not properly varnished they would spoil. Great care should be taken to wash them clean from the hyposulphite, or they would be destroyed; but the greatest trouble arose from the varnish. He had, in one establishment, seen them all, three different kinds of varnish, but all the pictures were destroyed. There was a "flint varnish," manufactured by Mr. Anthony, which he found to work well.

Mr. HULL had used equal parts of seedlac and shellac, and warmed his plate well. Occasionally, if the varnish was brittle, he added a little Canada balsam. This he had never known to fail. He generally took seedlac in an ordinary glass globe, put in alcohol, boiled down, by adding seedlac with shellac until he had quite a syrupy mass, which he kept, diluting at a time enough to last a couple of weeks.

Professor SEELY: Is it the common red shellac you use?

Mr. HULL: No; I use a good quality of bleached shellac. About a month ago he had occasion to use a negative which was laid by for a year, then in perfect condition; when taken hold of, it was all broken up in many lines and long blisters. But this instance he attributed to imperfect washing.

Mr. BURGESS inquired if any one had heard of the process of printing with mica, and not varnishing at all? He had read of its being done in England. It was true all negatives printed better without any varnish, if it could be done, the varnish changing them to some detrimental degree. Some skillful man had used a thin layer of mica; but that was attended with great difficulty. Some have used gum arabic, which does not affect the picture at all. It is put on before the plate is dry. But he had put gum arabic over them, and let the picture stand two months, and it surely spoiled. It was only proper to use it when they wanted to use the glass in a short time. There was certainly a great defect in the varnishes used.

Mr. HULL said one of the most successful practical photographers in Philadelphia kept his negatives by using albumen in solution. One of the troubles in regard to varnish arose from the fact of its being put on too thick; it should be used as thin as it could be, and have a thin surface.

Mr. TILLMAN judged that one of the difficulties would be, that putting on a liquid on such a fine work as a negative must interfere with the picture. It struck him (and he threw out the suggestion for practical photographers) that it would be better to put on the varnish in the shape of vapour, at first

thus obtaining a fine coating that could not be had in the usual form.

Mr. CRUM said it had occurred to him whether the fault was attributable altogether to the varnish or to some other process in making the negatives. Out of a large collection he had bought he found some preserved remarkably well, fine, very intense, clear, and transparent, and apparently as good as the day they were varnished and laid away. Others, with apparently the same kind of varnish were very much affected, rusty, and having a tendency to peel off, spotted, and badly scratched. Whether this was owing to bad handling before the negative was laid away, or was attributable to the varnish, he was not able to say, but among those piled away he had found some of the worst, while among those piled up promiscuously some were very fine. Some varnish, when put on the plate, after being heated, will dry very unevenly, and notwithstanding all precautions he found the negatives badly spoiled. In the last number of the *Journal of Photography*, he saw that a correspondent inquired in regard to this very difficulty. He thought, so far as his limited experience went, that it was owing to the breath depositing moisture on the plate when varnishing.

Prof. SEELY believed that in respect to varnish we had, in this country, been more fortunate than our neighbours in Europe. For the first four or five years of collodion working, the varnishing question seemed to be the most important; there were any quantity of inventors of varnish, and probably there was nothing known in that way that was not used. The chloroform amber varnish was invented, and the difficulties supposed to be removed. But amber varnish was found not to work well in this country. Here copal spirit varnish came into use at the first, and continues still to be used. It was better at the start than it has been generally made since. For a number of years it was the only varnish used, according to his recollection. Then some worthy gentleman discovered that shellac was nearly as good, and that was put into use. Later, benzole was used as a solvent, but he did not know of any varnish, in this country, where benzole was used, that was good for anything. He thought the varnish sold for "negative varnish," by respectable manufacturers, was all right, and that some of the imperfections charged upon the varnish was with the individuals themselves. He had learned after years of experience, and he had been told that one of the most difficult things to do was to lay varnish evenly. He had taken some thousands of prints from a single negative made years ago, without deteriorating the negative, and it was perfect enough at this day. He had often seen gum arabic used, but he thought albumen a good deal better. One of the former difficulties with varnish was that it was used too thick.

Mr. HOLZ gave the proportions of the varnish used by him as six ounces bleached shellac, four pints alcohol, and three ounces gum sandrac, filtered carefully through paper. This was a good varnish, still he found that it did not always answer the purpose. He did not think it would be well to print negatives without varnishing, for we could not get any wear or tear out of them. Pictures which were too intense were benefited by the varnish.

Brass Toning.—The subject of brass toned pictures having been introduced,

Mr. HULL said that Mr. Thompson did not claim to tone his prints with brass entirely. He did not use exact proportions—he merely used brass in connection with gold to a very trifling extent. Mr. Thompson made excellent prints, but it was by admirable manipulation.

The members expressed a good deal of incredulity as to the feasibility of toning with brass.

Mr. TILLMAN thought that, until some members made experiments, a discussion on the subject was unprofitable.

Polar Expedition.—The following was, on motion of Mr. TILLMAN, adopted:—

Whereas, The members of the Photographical Society have heard, with great satisfaction, that Mr. Washington Peale is about to accompany Captain Hall upon another Polar expedition; therefore,

Resolved, That this Society will take an active interest in the scientific objects of the expedition, and will especially contribute towards the photographic branch of the service, by any means in its power.

Resolved, That this Society hereby solicits contributions of money and photographic materials, in aid of the undertaking.

Resolved, That the Society wish Mr. Peale, and the other

members of the expedition, God-speed and a safe return, from the perils of the Polar seas.

Two subjects were designated for the next meeting: Lenses, and the Influence of Coloured Glass on Vegetation.—*American Journal*.

FORMIC ACID.

BY Z. J. GODIMUS.

Two acids are now being put to the proof by photographic chemists: they are formic acid and tartaric acid. We give the result of experiments made at different times during the last two years. We shall first notice formic acid; especially as it will give us an opportunity of recalling to mind some general ideas susceptible of giving a better comprehension of the nature of this photographic product.

Chemists have at first contended this acid with acetic acid. The first has a formula of $C^1 HO^1$, HO , and the second and $C_1 H O_2$, HO ; they can obtain both from the reaction of the chemical elements of alcohol upon very divided platinum; oxidation takes place at the expense of the oxygen of the atmosphere. Formic acid and acetic acid enjoy, besides, analogous properties, both physical, and chemical, and organoleptic. We can then understand the error of our predecessors in science. We pass over in silence the two scientific developments, regretting we cannot give them, compelled as we are to keep to the practical side.

Formic acid ($C^1 HO^1$, HO) is thus named because it was first obtained by distilling ants with water. The liquid, collected in a receiver, was saturated with carbonate of soda. ($Na O, CO^2$): afterwards evaporated to dryness, then distilled again, the salt dissolved in a liquid composed of equal parts of sulphuric acid and water (by weight). Such was the first preparation.

The acid thus obtained was monohydrated, as the formula indicates. It is difficult to procure it in the anhydrous state, and as we cannot perceive to what an anhydrous combination will lead us when we introduce this acid into an iron developing solution, we ought to give the plate less exposure in the camera. This monohydrated acid is liquid, colourless, and very corrosive: it blisters the skin instantly. It boils at $212^{\circ} F.$, and in every condition is volatile, very acid, with a vivid, penetrating odour. It is very greedy of oxygen, and instantly reduces the salts of gold, silver, and mercury. United with concentrated sulphuric acid at the ordinary temperature, it is converted into water and oxide of carbon, which essentially distinguishes it from acetic acid.

We have actually arrived at a great diminution in the time of exposure—that is to say, where we used to give four minutes exposure we now give only one minute, and obtain as good results. We always take care to add our formic acid to our developing solution only at the moment of using it, and the liquid dowing off the plate was rejected. Lastly, we made use of monohydrated formic acid. The following is the formula employed:—

Purest Distilled Water	100 parts.
Refined Protosulphate of Iron ...	5	"
Monohydrated Formic Acid ...	$\frac{1}{2}$	"

We entertain no doubt that, all the conditions being well observed, this bath will permit of the developing instantaneous pictures which have been taken in a good light.—*Bulletin Belge de la Photographie*.

Photographic Notes and Queries.

NON-ACTINIC WEATHER.

DEAR SIR,—May I inquire of your numerous readers, whether, during the past and present week, they have noticed any peculiarities in the state of the atmosphere; as with us, at Ross, from 10 o'clock a.m., until 5:30 p.m., we can get no pictures without exaggerated exposures and an immensity of intensifying.

Many may urge the bath, the collodion, the developer, as being in fault. I would state that the same occurs with baths newly made with Sutton's recrystallized nitrate; with Johnson and Mathey's samples of silver added to which the baths that on Saturday last gave brilliant results, the same now give pictures, it is true, but they are flat and poor. Of collodions I have the same results with Ponting's, Sutton's, Mawson's, Horne and Thornthwaite's, (by the bye their collodion is A 1.), and Perry's—the same with many of these mixed. Whether the developer be 10 grs. or 50 grs., whether with acid, without acid, or with formic acid, the results are precisely the same.

There seems to be a want of electricity in the air: many around us are complaining of pains and giddiness in their heads.

Now, I should like to know whether such is felt and found in other parts of England; whether at the seaside or only inland? Perhaps some of the numerous readers of your widely published journal would give us their ideas upon the matter.—I am, dear sir, yours,

W. H. WARNER.

Ross, 8th July, 1863.

Miscellaneous.

IMPURITIES IN THE NITRATE OF SILVER.—Certain photographers are very apt to blame the nitrate of silver as soon as they get into trouble. They should be cautioned against this. We can safely say that the nitrate of silver sold by our leading stock dealers is faultless; and what is true of nitrate of silver is equally so of all other photographic chemicals. Some photographers, however, supply themselves at the country drug stores, and for the benefit of these we will say a few words of the impurities ordinarily found in commercial nitrate of silver. Crystallized nitrate of silver may be acid, and when acid, it contains often a small quantity of organic matter. A bath made with such an article will be apt to work foggy. The test for acidity, everybody knows, is litmus paper. When this turns red in the solution, add to it some oxide of silver, and set it in the sun for one or two hours. Then pour off the clean part, filter and add a drop or two of nitric acid. Fused nitrate of silver gives baths which will only work clear after adding several drops of diluted nitric acid. Nitrate of silver may be mixed with nitrate of potash, or other alkaline nitrates. In this case there is a loss in quantity only, as the presence of these substances does not unfit the bath for photographic operations. Pure nitrate of silver precipitates its weight of iodide of potassium. This furnishes a simple means of testing, if it contains the required quantity of silver. Proceed as follows:—1st. Dissolve 40 grains of the salt to be tested in two ounces of water; 2nd. Dissolve also 40 grains of iodide of potassium in two ounces of water; 3rd. Dissolve 16 grains of nitrate of silver, which you know to be pure, in two ounces of water; 4th. Mix the first and second solutions together; a yellow precipitate of iodide of silver will be formed, which will settle, leaving the liquid slightly troubled, it containing little yellow iodide of silver in suspension. An addition of the third solution will clear up the liquid. When only a few drops have to be added to accomplish this result, the nitrate of silver may be considered pure. But when larger quantities are added, without clearing up the liquid, the salt is probably mixed with some other nitrate. To determine how many grains of nitrate of silver are short, add one drachm at a time of the third solution, shaking, after each addition until the liquid becomes clear. The number of drachms to be added will represent the number of grains of nitrate of silver short.—*American Almanac of Photography*.

Talk in the Studio.

PHOTOGRAPHY AND FORGERY.—Pietro Regnoldi, an Italian, was recently brought before the Lord Mayor, charged with causing to be forged a one-guilder note, with intent to defraud the Emperor of Austria. It appeared that on the 18th ultimo the prisoner went to the residence of Mr. McQuire, of 4, Aldgate, photographer, about seven o'clock in the evening, and asked to

sent a specimen of phot. graphy. Several were shown him, with which he was apparently satisfied, but he left without having his likeness done, promising to call next morning, which he did. Two portraits were then taken of him, after which he asked M-Quire if he could copy works of art, and, when answered in the affirmative, he expressed much pleasure, saying that he had heard a very favourable account of him, and he would give him some work, which would bring him in lots of money. He then produced a one-guinea note, and asked the photographer whether he could take an impression of that upon glass, so that it could be reproduced. M-Quire said he could. He then left the note in the possession of the latter, charging him on no account to let any one see it, but when it was prepared to give it back to him, and he would have 1,000 struck off, and if they were successful they would do some more of greater value. He also asked M-Quire if the paper could be procured in London, and, on the witness telling him he did not know, he said it was not of much consequence as they could get it abroad. M-Quire then communicated with the police, but in the meanwhile he photographed the guinea note with which the prisoner was very pleased, and gave him six napoleons, together with a five-guinea and a ten-guinea note, which he wished to be photographed in the same manner, and, when they were all to be completed, he directed his (as he thought) accomplice to get the whole three engraved, so that they could at once commence to strike them off, telling him, at the same time, that when they were done they would proceed to the Continent together, where they could make their fortunes in six months; after which they might retire to America or Australia, where they could live a life of ease and pleasure without fear of discovery. These anticipations were, as the prisoner thought, just about to be consummated, when he was taken into custody. On his person several guinea notes were found, together with forty-two golden napoleons. The prisoner was again remanded.

GLASS BATHS.—We have received from Messrs. Claudet and Houghton a sample of a new form of glass bath, which is, in several respects, superior to those hitherto made. One essential improvement consists in a lip from which to pour the contents without spilling, an operation almost impossible with the ordinary straight-sided vessels usually made in glass. The lip does not in any way interfere with the application of the water-tight cover, as there is no depression of the top where the lip projects; the whole is ground level, and may easily be fitted with the cover. The bath is better made and stronger, especially at the bottom, than most glass baths we have seen.

INSTANTANEOUS DRY PLATES.—We have received from Mr. Hurst, of Mirfield, some few slides taken on plates prepared by a modification of the tannin process, which is manifestly very rapid. Two of the plates have had instantaneous exposures. A cow grazing in the foreground has not moved, a boat is being rowed down the stream, foliage in the mid-distance is made out, a distant town well defined, and the whole crowned with good clouds. A little longer exposure would have been better, but the result is remarkable for dry plates. Mr. Hurst employs Dallmeyer's new stereo lenses, and probably a large aperture has been used. Mr. Hurst, speaking of the slides, says:—"Two of the views of Knaresborough were exposed instantaneously; they are not good pictures, but they show the sensitiveness of the plates in giving even details of foliage at the same time as clouds. Had they been exposed at the seaside with water and sky only to be impressed, I have no doubt they would have been perfectly successful. Most of the plates had been prepared some weeks and were not developed (even the instantaneously exposed ones) until 6 or 7 days after exposure."

To Correspondents.

PHOTOS.—We do not recommend you to adopt the hypothesis, but if you do, it, after carefully reading it, is of few hours' bearing. 2. The advantages claimed for the saccharin process are that it is a titanic process, and that it gives a different and more distinct image. See page 2. 3. Precipitate the cover as chloride with common salt. 2. Tanning of albumen prints is effected with water. 4. A mixture of soda, Bichromate, and neutral tint will be found equally to answer the purpose. Of course it is necessary to match the colour of the print, and a little gum water will be found to mix with the colour to give it a little gloss, and then wash when dry. 3. The tanning baths containing lime generally give a better result. 4. **J. BARNEZ** says:—"Can you kindly inform me how to remedy hardiness

coming from the bath. I had a negative bath which gave beautifully soft pictures for two months. It then gradually began giving pictures harder and harder day by day. I have tried every known remedy, making it alkaline with oxide of silver and tanning for ten days, tried it faintly acid, very acid, neutral, still hard pictures, strengthened it, weakened it, always with the same result, overdarkness in the high lights. I use a strongly bromized collodion, the usual iron developer, intensifying with citric acid and iron. On first developing the latent image the high lights shoot out, and the half tints only make their appearance after prolonged development, whatever the exposure may be. As I never was so troubled before I should like to know the probable cause and the remedy if any. Up to the present, I had never had a bath 'out of order' longer than 20 or 30 minutes." The case described is a complete anomaly: for a bath to give precisely the same class of pictures whether it be alkaline, neutral, or acid, and with whatever exposure to give hard pictures with a highly bromized collodion, is an experience we have never met with. Using oxide of silver is sometimes very deceptive. If it be not fully precipitated it will sometimes remain a very long time in the bath without injuring it. Although its use is the most philosophical plan of neutralizing the bath, we now generally recommend the use of bicarbonate of soda as giving less trouble and more certainty. Again, what acid did you use? What acid did the bath originally contain? If acetic acid, the addition of oxide of silver would form acetate of silver, which would readily account for the results you describe. Are you quite certain it is the bath and not the collodion which is in fault?

J. H. B. KERR.—The bleaching in the prints considered is, doubtless, due to excess of free chlorine. When the tanning solution is required to be used soon after mixing the portion of chloride of lime added should be very minute. Age always, up to a certain extent, appears to improve the lime bath, but what is the exact process which goes forward to produce the improvement we are uncertain. The process with carbonate of soda, as described by Mr. Elliot, is very excellent, but does not give quite the same tones as the lime bath.

P. T.—Paper prepared with bichromate of potash and gelatin, or any similar organic body, when exposed to light, first assumes a brown tint, and then a greenish hue. Neither of the colours obtained have in themselves any pictorial value. By a combination with other metallic salts, however, a variety of tints may be obtained. You will find some interesting details in a paper by Mr. Hannaford, on page 341 of the third volume of the PHOTOGRAPHIC NEWS. The chief value of the bichromates is found in the various carbon and photolithographic processes, where the fact that a compound of organic matter and a bichromate is rendered insoluble by the action of light, becomes of the highest importance. 2. Water colours, with a little gum or albumen added, should be used for touching out spots in albumenized prints.

J. S. V. L.—The chief photographic fault of your specimen is a little under-exposure of the negative, and the chief artistic faults are a pale ground in the position and a too "loud" or obtrusive background.

A. STREKER.—It has been asserted by some authorities that the use of bromo-iodized collodion in a silver bath suits it for subsequent use with simply iodized collodion. We have never found any such datum in the bath, but if we did we should not regard it as a matter of consequence, for we should never think of using other than bromo-iodized collodion, except for special experiments.

T. INGLEBY YATES.—In our recent article on altering the intensity of varnished negatives, we explained the method of reducing intensity. It consists in continuing the action upon the varnished film, of the alcoholic solution of fuchsine, until the deposit is inverted into white, or light yellow instead of silver.

LES. DART.—Procure a blank form provided at Stationers' Hall, and send for a penny a fillip with a brief, but intelligible and characteristic description of the picture; proceed to the Registering Office, and pay one shilling for each photograph to be registered, or forward the form with fillip in place for each photograph, to our publisher, who will undertake the trouble for you. You will find full information in our last volume, and also in the present year's PHOTOGRAPHIC NEWS ALMANAC.

G. F.—The excessively acid state of your bath is, doubtless, the cause of the film leaving the plate. A more adherent sample of collodion may prove a remedy; but you had better direct the amateur.

M. T. H.—Print deeper and tenebrous, if your air-bark tones. Your vignette pictures are too formal in the graduation of white, a more natural effect will be visible in glass. To vignette well requires the use of care, taste, and colour well.

J. H. INSKIP.—Your advertisement arrived too late for our last. Several correspondents in our next.

LIME TONING BATHS.

PHOTOGRAPHERS are generally craving for some improvement in the process of toning. They have two requirements: one, a process which shall tone with ease and certainty, and be characterized by simplicity; another, that it shall give them black tones if necessary, and add the utmost vigour and brilliancy to their prints. The first demand is easily understood; simplicity and certainty are so valuable, that every practical man desires them. The second demand, the black tones, arises rather from the tastes of the public, who frequently object to warm tones, especially browns. They prefer the black of an engraving, which has become the conventional type of monochrome in demand. The sepia and bistre drawings, and the warm-toned aquatints which were at one time popular, have largely passed out of fashion, and black tones are most commonly admired.

The various lime baths have the reputation of most readily yielding black tones; but a great difficulty is frequently experienced in getting good results without undue bleaching, and, in many cases, mealiness. We have often published formulæ for lime baths, which have, in the hands of some of our correspondents, and in our own, given admirable results, but which have, nevertheless, as we have subsequently learned, when used carelessly, or without due attention to instructions, given bleached, mealy, poor prints. The only remedy we can point out in such cases is a recognition of the fact that free chlorine is the cause of bleaching and mealiness, and where these faults are present there are two remedies: either to reduce the quantity of free chlorine, or to allow the bath to become older before use.

We have recently had an opportunity of inspecting the prints produced by a lime bath, of which we subjoin the formula, which appeared to give the most uniform results of any we have witnessed. On our way to Paris we called at the establishment of Mr. Parkinson, of Dieppe, an English artist settled in France. We there examined many hundreds of prints in different stages of completeness; and apart from the extreme excellence of the photography, we may state that we have never before noticed such perfect uniformity of tone as these prints presented. The tones were throughout of a rich warm black, giving, by virtue of the intensity of colour, the greatest possible brilliancy to delicate prints. This black prevailed throughout, never verging into blue, never suggesting red or brown. A rich, deep, warm black in the deep shadows, with a warm, fleshy effect in the lights and half-tones.

The method of toning we learned was one arrived at by gradual modifications of Ommegeanek's formula, the object having been to secure its advantages with greater simplicity. The method was as follows:—A saturated solution of chloride of lime, with also as much carbonate of lime as it will dissolve, is kept ready mixed. Of this solution, five grammes, equivalent to a little more than a drachm and a quarter, are

added to a litre (35 ounces) of water, to which is added two grains of chloride of gold. The toning solution thus made is very weak; it may be used within a few hours of mixing: but is better used next day, and will keep a few weeks. The paper is excited on a strong silver bath, and a little over-printed, but not very much. A large number of prints are immersed in the toning bath at once, and left with only occasional attention, as there is scarcely any danger to be apprehended to render watching necessary. Nearly an hour sometimes elapses before the print has obtained the deepest black which can be obtained, and even if left longer it does not readily pass into the slaty blue tint of over-toning.

It will be seen that a solution of chloride of lime, if long kept and not closely stopped, would gradually change its character; carbonic acid being absorbed, and carbonate of lime being precipitated. But this need not happen to an appreciable or hurtful extent if due care be used.

Mr. Parkinson's vignettes were especially charming, and derived immense value from this tone. He worked with great rapidity, he informed us, using a Dallmeyer's No. 2 B lens, which gave him infinite facilities in obtaining simple, easy, natural expressions, which long exposures render impossible.

PHOTOGRAPHS IN THE LAST CENTURY.

A SINGULAR and striking corroboration of the probable authenticity of the photographs alleged to have been produced by James Watt, in the latter half of the last century, nearly half a century before the discoveries of Talbot and Daguerre, has just been discovered in the shape of contemporary photographs. All persons acquainted with the history of photography are familiar with the fact, that Wedgewood experimented largely in the production of sun-pictures, and the impression generally obtains that he was successful up to a certain point. It is well understood that he succeeded in producing pictures by the agency of light. He was, we believe, the first who experimented with the solar microscope for this purpose. Up to the present moment, however, it is understood that he did not succeed in fixing, or giving permanency to any of the pictures he obtained. From trustworthy information we have just received, it appears that two of the sun-pictures of Wedgewood, in a perfect state of preservation, have just been discovered.

A lady, well-known in literary circles, who is engaged in the preparation of a biography of Wedgewood, and who has had access to long-buried documents belonging to the deceased *savant*, has found, stored with these papers, two examples of the sun-pictures he produced, together with details of their mode of production. The full historical particulars, together with the technical details, will be published in the "Life of Wedgewood," now in the course of preparation, which will, doubtless, be looked for with interest. We hope shortly to place further information on the subject before our readers.

PHOTOGRAPHY IN PARIS.

WILLEME'S PHOTO-SCULPTURE.

AMONGST the many important applications of photography we know of none more ingenious and interesting than the invention of M. Willeme, to which he has given the name of photo-sculpture. The title is probably familiar to our readers from occasional extracts we have given from French journals and the allusions of our Paris correspondent. The subject had interested us, but we had not so fully realized the *modus operandi* from published accounts as we wished. The method, as described, seemed very complicated, and possibly it may continue to do so to our readers after we have given our description. Nevertheless, in practice it appears beautifully simple and efficient.

M. Willeme is a sculptor of considerable ability; and having derived great aid from photographs as guides in the production of portrait statuary he was led to the ingenious and extended application of our art, the manipular details of which we had recently an opportunity of witnessing. Accompanied by our good friend, M. Ernest Lacan, whose introduction was the *open sesame* to every part of the studio, we first visited the gallery of specimens, consisting of busts and statuette, in various sizes, and some photographs presenting the odd effect of betwixt twenty and thirty full-length portraits, all different views of the same person mounted in succession on one card. Here we learned how the rapidity and ease of the process cheapened production, a full-length statuette, about twenty inches high, costing, we were informed, three hundred francs, or little more than twelve pounds sterling, not more than one-fifth of the cost we should imagine of a similar work produced entirely by hand labour.

We now entered the glass room, which is circular, about thirty feet, or a little more, in diameter, and surmounted by a glass dome. In the centre is a stand upon which the sitter is placed. This stand is polygonal, having twenty-four faces, each duly numbered. Placed at twenty-four regular intervals round the room are twenty-four cameras, the apertures of the lenses alone being seen, each aperture corresponding with one face of the stand upon which the sitter is placed. The sitter being duly posed in suitable position by the sculptor himself, twenty-four wet collodion plates are, by a clever contrivance, exposed simultaneously, securing twenty-four negatives, each with a different view of the sitter, and the number of each negative registered upon it, as given by the face of the polygonal stand. The negatives, securing all these views of the sitter at the same moment, are now ready for the guidance of the sculptor. We shall next see the use to which they are put.

Proceeding to the modelling-room we find M. Willeme himself, engaged upon a life-sized *bas-relief* of the *Duc de Morny*, and two assistants upon a full-length statuette about twenty-four inches high of the same nobleman. The operation is as follows:—A small block, having twenty-four faces duly numbered, being in all respects a counterpart, on a smaller scale, of the central stand in the glass room, is provided to receive the modelling clay, roughly formed into a cylinder of the proper dimensions. Immediately adjoining it is a large ground glass screen, upon which an enlarged image of each negative in succession is projected. We will suppose negative No. 1 is so projected; the side of the block, containing the modelling clay, also marked No. 1, is brought into proper position. A pantograph, suspended in a convenient position for use, is now brought into operation. With one arm the outlines of the negative are traced by one workman on the ground glass, whilst the other arm, furnished with a cutting point or needle, follows the outlines of the negative, making an incision in the modelling clay. This operation completed, another negative is substituted, and the corresponding face of the block brought into position. It does not follow that the next negative will be No. 2; on the con-

trary, it will probably be No. 7, the object being to get such an outline as will, when traced with the cutting point, exactly intersect the cut already made, and thus separate a wedge of the clay from the block. The operation thus progresses, a good deal of judgment and manipular skill being called into exercise at its various stages. When the operation is complete, a complete, roughly cut statuette has been produced by accurately following the photograph by means of the pantograph. It now only remains to be finished slightly by the sculptor, the trifling amount of his services which are necessary being best evidenced by the extremely moderate price at which a complete statuette can be produced.

The result of the finished work is singularly realistic. The absence of certain conventional characteristics, which so often belong to sculptured figures, especially to statuettes, is especially striking. The naturalness and lifelike effect of the photograph are here conferred upon the plastic clay, and the effect is unusually striking and satisfactory. The industry, ingenuity, and ability with which M. Willeme has brought his conceptions into working operation, and the perfection with which this beautiful application of our art is made to aid the sister art of sculpture, is worthy of the highest admiration and praise.

PHOTOGRAPHIC CHEMICALS:

THEIR MANUFACTURE, ADULTERATION, AND ANALYSIS.

PERMANGANIC acid is very remarkable in one of its properties: it is a volatile body, and can easily be distilled. If this acid were prepared in quantity, and could be generally procured in commerce, it would be a better disinfectant and deodorizing agent than even the potash salt so generally used under the name of Condry's fluid. When permanganate of potash is used to destroy organic matter, there is always a certain quantity of potash left behind in the water, increasing with the amount of organic matter oxidized. If permanganic acid be employed for a similar purpose, all the organic matter will be effectually destroyed, and there will be absolutely nothing given to the liquid but what can be removed by filtration. The carbon of the organic matter will be burnt into carbonic acid, the hydrogen will become water, whilst the permanganic acid will be reduced to the state of peroxide of manganese, an insoluble powder capable of removal by filtration.

Permanganic acid is not difficult to make. By adding a teaspoonful of oil of vitriol to a wineglassful of strong solution of permanganate of potash in a dish, Mr. Condry states that there will immediately ascend from the vessel containing the mixture beautiful crimson vapours, which are permanganic acid set free by the action of the acid on the salt. Mr. Terrel has lately investigated the subject very fully. He finds that permanganic acid may be readily prepared by dissolving permanganate of potash in sulphuric acid which has been diluted with half an equivalent of water; adding the salt gradually, and taking care that the temperature does not get too high. The solution is of a yellowish green. This is then introduced into a tubulated retort connected with a well cooled receiver. The only special precaution required to be taken is that no corks or other organic matter must be used in the apparatus. The retort is placed in a water bath, and heated to a temperature not exceeding 60° or 70° C; if a higher temperature be reached, there is danger of sulphuric acid passing over. The apparatus now becomes filled with violet vapours resembling those of iodine. These soon condense in the neck of the retort to a thick liquid of a greenish-black colour, which consists of pure permanganic acid, containing neither sulphuric acid nor chlorine. There is a difficulty in preparing a large quantity of this acid at one operation. When the quantity of acid collected in the receiver begins to accumulate it decomposes spontaneously with a slight detonation, oxygen being evolved, and sesquioxide of manganese left behind.

This difficulty would be obviated by preparing the acid in small portions at a time, and repeating the operation. Many chemical preparations have to be made in a similar way.

If a few drops of water are added to the sulphuric acid solution of permanganate of potash, permanganic acid will be seen to float upon the surface of the liquid in the form of oily drops of a greenish black metallic lustre, which sometimes solidify and fall to the bottom of the liquid. It is difficult to separate this permanganic acid from the sulphuric acid which contaminates, but in this state it will serve very well for most purposes of oxidation. When pure, permanganic acid is a thick liquid, of a greenish black colour and metallic appearance. It seems to be capable of solidifying. It is very greedy of water. Its solution is violet, and it keeps pretty well when dilute and free from dust. If suddenly heated, it detonates, but if gently heated, part volatilizes, producing violet vapours, which possess a very disagreeable metallic odour. This acid is probably the most energetic oxidizing agent known. It instantly sets fire to paper and alcohol, the latter with explosion. In these combustions there are always produced violet vapours, due to the volatilization of a certain quantity of the permanganic acid from the intense heat evolved. When placed in contact with a fatty body, it detonates suddenly, with emission of a beautiful white light. In this case very little acid must be used, as owing to the violence of the action the explosion might give rise to accidents. A very beautiful experiment may be tried with permanganic acid by reacting on it with sulphite of potash. If a few drops of an aqueous solution of the latter salt are added to some of the permanganic acid formed in the sulphuric acid solution of permanganate of potash, a very lively reaction will take place with disengagement of light. A large quantity of acid is carried off in the form of violet vapours, which, meeting with dust and organic matter in the air, are reduced and fall down in the form of brown flocks, very light, similar to oxide of zinc when this metal is burned in contact with the air.

For all purposes in which water free from organic matter is required—and when is such purity not required in photography?—it is essential that some such agent as permanganic acid be employed. Photographers are too apt to rely upon the ordinary distilled water as being perfectly pure—in fact this term is frequently regarded as synonymous with *pure*, which is a great mistake, as ordinarily distilled water most frequently contains organic matter, and sometimes in sufficient quantity to produce very deleterious effects, when employed in delicate photographic processes. Were distilled water generally prepared on purpose—were the final object of the operation in which it is produced, the production of a water which should answer all photographic purposes, there is no doubt that such a result could easily be accomplished. But the case is far different. In most instances, distilled water is merely condensed steam from an engine or boiler, and is allowed to run into vessels set to receive it with no precautions whatever for preventing its contamination with organic matter. The consequence is, that common distilled water, although it may be free from chlorides or sulphates, has an amount of organic impurity in it sufficient, in most instances, to be detected by the smell and taste. This, generally, arises from the grease and oil which so plentifully abounds in the vicinity of steam machinery; but, whatever its origin, it is imperative that it should be got rid of. This is very easily effected by re-distillation from a glass retort, a little permanganate of potash being added to the water, but as it may happen that many photographers may not possess conveniences for distillation, the same perfect purification may be effected by adding a little aqueous solution of permanganic acid to the water, and then boiling violently in a glass flask until the pink colour of the liquid is removed. A brown powder of hydrated peroxide of manganese will be precipitated, and the supernatant liquid, after being decanted, will be as near

chemically pure water as is likely ever to be required, even in photographic manipulations.

Permanganate of potash is the chief source of this acid and its compounds. It is not difficult to make. It is prepared by the spontaneous decomposition of the corresponding manganate dissolved in water. Manganate of potash, owing to the changes of colour which it undergoes during decomposition when dissolved in water, is called *mineral chameleon*. It is formed when any oxide of manganese is ignited with caustic potash, or its carbonate, nitrate, or chlorate. To prepare it, take one part of very finely powdered peroxide of manganese, and ignite it with 3 parts of nitre, till a small portion of the mass taken as a sample and allowed to cool dissolves almost wholly in water, forming a dark green solution. The mixture will become semi-fluid during ignition, and finally assumes a pasty consistence. The crude product so obtained is what is generally known as *mineral chameleon*. It is a blackish green substance which yields a dark green powder, and besides manganate of potash may contain peroxide of manganese, potash, carbonate and nitrite of potash.

ON THE IRON DEVELOPER.

BY C. OMMEGANCK.

The composition of the iron-developing solution employed in photography is based upon the property possessed by the protoxide of iron of reducing the nitrate of silver to the metallic state.

All the salts of iron are not equally well adapted to this purpose. Of the various salts of iron with which we have experimented, the sulphate of the protoxide has given the best results. The acetate and the nitrate of the same base develop only a very feeble image, especially when the bath is recently prepared; when the solutions have become old, and a portion of the oxide is peroxidized by contact with the atmosphere, they develop more energetically, but they rarely give the same intensity as the sulphate: the image they yield is black, instead of a metallic yellowish grey, as obtained from the sulphate. We are of opinion that we must attribute the more powerful reducing action of the sulphate to the sulphuric acid, which forms one of the elements of this latter salt, having more affinity than acetic acid for peroxide of iron; consequently the peroxidation of the iron, at the expense of the salt of silver, is more active in the presence of the sulphuric acid. For a solution of acetate of iron, or of the protoxide of the nitrate, upon contact with the oxygen of the air, deposits the greater part of the peroxide, which is formed in the state of subsalt, while, with sulphuric acid, there is little or no deposit in the solution.

After various experiments, we believe that we can also point out another cause which produces a more complete image with sulphate of iron than with other iron salts, or other developers. At the moment when the iron solution comes into contact with the film of collodion imbued with nitrate of silver, a precipitate of sulphate of silver is produced in the substance of this film, the picture appears in the parts most influenced by light; these parts fix to themselves alone the greater portion of the metallic silver arising from the decomposition of the nitrate, if the latter remains in solution; but as it has been in part precipitated, and as its solution takes place only successively, the parts feebly influenced by light have time to develop their action more slowly upon the sulphate of silver they contain, and in proportion as they are dissolved in the iron solution, which gradually penetrates them. These ideas are not based upon a simple theory, they are fully established by the following experiments.

Sulphate of silver is almost insoluble in cold water: it readily dissolves in a solution of sulphate of potassa or soda, sulphate of iron, and especially sulphate of ammonia. When we pour on the bottom of a test-tube a concentrated solution of nitrate of silver, and we introduce, by gently floating on

to, and mixing with it as little as possible, a layer of one of the above-named sulphates, an abundant precipitate of sulphate of silver is produced; if, after this, we mix the two by stirring with a glass rod, we perceive that the sulphate formed is re-dissolved. When the sulphate employed is the ferric sulphate, the experiment is modified in the following manner: before mixture, only a slight metallic reduction is produced between the layers of different liquids; in proportion as we effect the mixture by a slow agitation, the sulphate of silver is reduced and dissolved, but it does not undergo decomposition so long as it floats in the solid state. If we make use of sulphate of iron and ammonia, we perceive that the metallic grain of the reduced silver is much finer than that produced by the action of sulphate of iron alone.

The proportion of ferrous sulphate varies greatly, according to the various formula for the developing solution. Generally, for negatives, the extreme limits are from 1 to 10 per cent., with equally variable proportions of acetic acid. In our own practice we employ $\frac{3}{4}$ per cent., increasing gradually to 5 in winter, with $1\frac{1}{2}$ per cent., of crystallizable acetic acid.

Recently it has been proposed to employ the double salt of sulphate of iron and ammonia in preference to the simple sulphate, and, finally, it has been found that there is no great advantage in this substitution. Generally, the true value of this modification is not well appreciated. It is said that the double sulphate does not undergo peroxidation in contact with the atmosphere, like the single sulphate. True, in the crystallized state, the double sulphate is a very stable salt, with a clearly defined composition, but when dissolved, it absorbs oxygen just the same as the other salt; in this respect, therefore, there is no advantage; besides, there is a simple sulphate of iron, well crystallized and very dry, which is as pure as the double salt; it is obtained by washing the crystals with alcohol at the moment when they are withdrawn from the mother waters.

Few of the journals which have mentioned the employment of the double salt have shown photographers the equivalent quantities of the two salts; for in preparing an iron solution of four per cent. of double salt, there would be only about three per cent. of ordinary sulphate. The formula of the ordinary sulphate gives us the following proportions:—

The formula of the double sulphate is:—

so that 196 parts of double salt contain 139 parts of ferric sulphate. Dividing 196 by 139, we obtain 1 and $\frac{4}{10}$ ths per cent. of double salt, which should be substituted for the simple salt; for a bath of 3 per cent. it should be $4\frac{2}{5}$ per cent., and for a bath of 5 per cent. it should be 7 per cent. of double salt. The double salt is prepared by dissolving in water, with the aid of heat, 139 parts by weight, or an equivalent of crystallized sulphate of iron, and 66 parts by weight, or an equivalent of sulphate of ammonia. Filter the solution, and leave it to crystallize.

According to the experiments published by some photographers, the action of the double salt will be less energetic, less subject to produce fogging. Our own experiments have taught us that the difference of action of the two salts, during the first period of development, is scarcely perceptible, but the employment of the double salt permits of keeping the iron solution upon the plate much longer, and even of renewing it without having to fear fogging with large crystallized particles, which are produced by leaving the iron solution to remain an unreasonable time on the plate while developing. It gives a certain advantage in producing more detail in the shades.

There exists also another degree of hydration of the ferric sulphate, which is the monohydrated sulphate.

It is very necessary to prepare an iron solution strictly proportioned: it is obtained by throwing some alcohol into a saturated solution of sulphate of iron; a white powder is precipitated which is the sulphate with an equivalent of water: it keeps well, its composition is always constant. 85 parts of this salt correspond to 139 of ordinary sulphate, or, in round numbers, 6 parts of monohydrated salt to 10 of ordinary sulphate. It can be easily weighed, because it is in very small crystals, and for the same reason it dissolves in water immediately, in the preparation of the developing solution.—*Bulletin Belge de la Photographie.*

PHOTOGRAPHIC COLLODION: THE SALTS IT SHOULD CONTAIN, AND THEIR PROPORTIONS.

BY CHARLES HEISCH, F.C.S.*

A good collodion should contain from five to eight grains of pyroxyline to the ounce. A pyroxyline, of which six grains cannot be dissolved in one ounce of mixed alcohol and ether without making it too thick to flow readily, will not make a really good collodion. The best proportions of ether and alcohol are, as a rule, equal quantities of each. Four drachms of ether and two of alcohol should be mixed, and the six grains of pyroxyline added, to make the plain collodion; the requisite quantity of iodide, &c., should be dissolved in the remaining two drachms of alcohol, and the collodion, after getting clear, added to them, to make the ounce of prepared collodion.

The nature and proportion of the iodides and bromides employed, should be regulated by the use to be made of the collodion. Where only black and white subjects, such as engravings, are to be copied, a simple iodide, or an iodide with a small quantity of chloride to increase the intensity of the blacks, is all that is necessary. Bromide of silver, being more readily affected by light of various colours than iodide, and giving also much greater delicacy of half-tone, a bromide should always be employed in conjunction with an iodide, either for landscape or portrait collodion where the best possible results are desired. The qualities which it is most desirable to unite in order to form a perfect collodion, are the maximum of sensibility to light, not only white but coloured, and the power of bearing an exposure sufficiently long to bring out the detail in the deepest shadows, without becoming solarised in the lighter parts.

Much discussion has recently taken place, as to whether the presence of bromides increases the sensibility of collodion, and many contradictory assertions have been made on the subject. I believe these contradictions are mainly owing to the fact, that but few of the experimenters have paid any attention to the proportion of the bromide to the iodide, or of both to the quantity of pyroxyline in the collodion. To attain the maximum of sensibility, the collodion should contain, after being sensitized, as much silver (whether as iodide or bromide), as can be retained firmly by the film. If it contain less than this, the silver salts are so surrounded by pyroxyline, as to be comparatively insensible; if it contain more, the silver salts wash out into the bath, and leave streaks on the film. It is universally admitted that in the daguerreotype process, bromide, in conjunction with iodide of silver, is far more sensitive than iodide alone. The reason of this universal admission I believe to be due to the fact, that a very slight difference in the proportions of iodide and bromide in this process renders a plate not only less sensitive, but almost insensitive, so that daguerreotypists were obliged to pay that strict attention to proportions, which the experimenters in collodion have many of them failed to do, and hence, I believe, has arisen the discrepancies in their opinions.

A careful consideration of the very slight difference of

* From "The Elements of Photography."

proportions which so completely altered the state of a daguerreotype plate, convinced me that it could only be satisfactorily accounted for on the supposition that there is a real chemical compound of iodide and bromide of silver, which possesses in an eminent degree the two qualities of sensibility, and resistance to solarisation. Many experiments led me to the same conclusion. In 1851, I made a long series of experiments to see if iodides and bromides mixed in the proportion of their chemical equivalents, would not give those two properties both to paper and collodion in a greater degree than if they were mixed at random; and I arrived at the conclusion that in all cases a mixture of two equivalents of iodide to one equivalent of bromide, was far more sensitive than iodide alone, or any haphazard mixtures of the two. These experiments were repeated some years after, and the results exhibited at a meeting of the Blackheath Photographic Society. In all the collodion experiments, the quantities of iodides and bromides employed were so arranged, that six grains of pyroxyline were mixed with either iodide or bromo-iodide of silver, equivalent to 4.2 grains of silver, so that the experiments were strictly comparable. No subsequent experience has in the least modified my conclusions on this subject.

The nature of the base with which the iodine and bromine in collodion are combined, exerts a remarkable influence on the character of the sensitive film. Comparatively few bases can be employed, more especially where both iodides and bromides are required, as many iodides, and more bromides, are insoluble in alcohol and ether. The salts most available are those of ammonium, cadmium, lithium, magnesium, potassium, or zinc. Of these, potassium (the first employed), has now gone almost out of use, as the iodide is but sparingly soluble in any but weak alcohol, and the bromide almost insoluble. The salts of cadmium possess the advantage of being very stable, so that collodion prepared with them may be kept ready iodized for an almost indefinite time without change, a great advantage to those who only work occasionally. The greatest sensibility appears to be obtained by the use of those salts whose chemical equivalents are the lowest, which in fact leave the silver salts in the state of greatest purity in the film. Thus the salts of lithium, magnesium, and ammonium, give the most sensitive collodions, 6.43 parts of lithium, 12.67 of magnesium, and 18 of ammonium, being respectively equivalent to 55.74 of cadmium, and 39 of potassium. A great advantage also possessed by the salts of lithium and magnesium, is that the compounds formed by them on immersion in the bath of nitrate of silver are deliquescent, so that they tend to keep the film moist. On a hot day a plate prepared with a cadmium collodion, will in a given time be so dry as to render it almost impossible to pour the developing solution over it, while one prepared with magnesium or lithium collodion will be quite moist, and allow the developer to flow over it without difficulty. The following are the formulæ for collodion and iodizers which I found most useful:—

COLLODION.			
Pyroxyline	48 grains.
Ether	4 ounces.
Alcohol	2 "
IODIZING SOLUTIONS.			
No. 1.			
Iodide of Ammonium	30 grains.
Bromide of Ammonium	10 "
Alcohol	2 ounces.
No. 2.			
Iodide of Cadmium	38 grains.
Bromide of Cadmium	14 "
Alcohol	2 ounces.
No. 3.			
Iodide of Magnesium	29 grains.
Bromide of Magnesium	2.5 "
Alcohol	2 ounces.

No. 4.			
Iodide of Lithium	27.5 grains.
Bromide of Lithium	9 "
Alcohol	2 ounces.
No. 5.			
Iodide of Ammonium	40 grains.
Chloride of Calcium	3 "
Alcohol	2 ounces.

The ether and alcohol employed for this purpose should be pure and anhydrous. In mixing the collodion and iodizer the former should always be poured into the latter, as alcohol is the real solvent of the iodides, and if their solution be poured into a large quantity of collodion, some of the salt is often precipitated by the excess of ether present.

It is better never to use collodion till it has been iodized at least 24 hours. When the cadmium iodizer is employed, it should be kept much longer, it goes on improving for many weeks. The iodizer, No. 5, I employ principally where only black and white objects have to be copied, and when it is desirable to obtain great depth in the blacks, and purity in the whites, as in copying engravings, &c.

Should a thinner collodion be required, the quantity of iodides and bromides employed must be decreased in the same proportion as the pyroxyline, or the whole may be thinned after iodizing, by the addition of a mixture of equal parts of ether and alcohol. Should the collodion become too thick by use, it may be restored to its original consistence by the addition of the same mixture. In very hot weather it is sometimes well to increase the proportion of alcohol, and diminish that of ether, but as a rule, the above proportions answer the best.

A SHORT LESSON IN PHOTOGRAPHY.—No. 14.*

My instructions hitherto have been limited strictly to the chemical and mechanical manipulations that occur in that department of photography denominated the *wet collodion process*. This process will ever remain the predominant mode of conducting photographic operations in the room; it is preferred too by many tourists in the field. The inconvenience, however, of dragging along, over mountain and valley, or of stowing away on steamer or on the cars, a complete miniature operating gallery, has suggested the idea of superseding all this trouble by the discovery of a *dry collodion process*. Several processes have been discovered, which are more or less successful, and very practical; but it must be confessed that the same degree of sensitiveness in the dry process has not yet been attained as in the wet process—instantaneous pictures are the result only of the latter. It appears natural for us to expect such a result; chemical combinations and reductions are effected most easily when the molecules of matter are in such a condition as to have freedom of locomotion by which new molecular arrangements can be formed in accordance with the new electro-chemical attractions and repulsions superinduced by the contact of dissimilar bodies.

For landscape, and especially for architectural photography, for copying, as well as for every case of still life, where the time of exposure is not important, dry plates are decidedly superior to wet ones, because of the uniformity of their condition during the time of exposure; wet plates, on the contrary, by desiccation are continually changing; and one of these changes, the concentration of the nitrate of silver during evaporation, is one of the causes that produce minute apertures in the film. The aim of a dry plate is to attain to a maximum of preservation of the sensitiveness for an indefinite time.

It has happened hitherto that the ratio of this preservation is inversely as the time of exposure, or probably in plainer terms, that the better the plate is preserved so as to retain sensitiveness, the longer the time required to be exposed to the actinic influence to produce a given effect. The theory, that is, the rational elucidation of the action of reduction in a dry plate, is still a problem; if the wet plate, after sensitization, be thoroughly washed, and then exposed, no picture is developed by the re-

* From Humphrey's Journal.

ducing agent;* but in the dry plate, the film is very carefully washed and then coated with some preservative agent, as it is called, such as albumen, tannic acid, gelatine, honey, syrup, infusion of malt, glucose, &c., and then, when otherwise properly prepared and dry, it will yield, when exposed and afterwards subjected to the action of a reducing agent, an intense picture. I say the rationale of this phenomenon is still a problem.

Some suppose that the albumenous, colloidio-albumenous, gelatinous, &c., film becomes permeable to the developer in the dry process, whilst the collodion film in its simple unpreserved condition is not so. Such a supposition is, however, the mere admission of our inability to render any satisfactory explanation.

As yet also it is a difficult task to say which of the dry processes in vogue is actually *the best*; although, perhaps, the majority would throw the weight of their opinion into the scale of the fannin process. The dry processes most conspicuously on the carpet are: the albumen process; the colloidio-albumen or Taupenot process; the gelatine, or Dr. Hill Norris's process; the tannin process of Major Russell; and the resin process.

The Albumen Process.

This process was in use several years before that of collodion; Niepce de Saint Victor first produced negatives with it. It is still employed by some of the most distinguished artists in the production of stereographs and photographs of interiors and pictures of still life. Its theory is very simple, but its manipulation demands great care and skill.

Formula for Iodized Albumen.

The white of egg	10 ounces
Iodide of ammonium	44 grains
Distilled water.			

Dissolve the iodide in the water, then add the solution by degrees to the white of egg entirely freed from the germ and yolk, and beat up the egg well with a wooden spatula until it is completely converted into froth. This operation must be performed in a place as perfectly free from dust as possible; and then the albumenous mixture is covered with a clean sheet of paper and put aside to settle for a number of hours. After standing the required time, the surface becomes covered with a sort of incrustation, through which an aperture is made to allow the iodized albumen to flow out. In some formulas for iodizing the albumen a bromide is used, and a small quantity of free iodine as follows.

Formula No. 2.

The white of egg	10 ounces.
Iodide of potassium	44 grains.
Bromide of potassium	15 "
Free iodine	2 "
Distilled water sufficient to dissolve the salts.			

Beat up with the white of egg as before. The operation is best performed when the temperature of the room is low. A few hours previous to the operation of coating the plates, mop the floor and wipe all the shelves with a damp cloth—the great trouble in the process is the deposition of dust or fibres on the glasses during the time they are drying. Another trouble—and these are about all the difficulties the operator has to contend with—is the flowing of the plate with an even and uniform film and its uniform retention on the plate until dry. The plates, of course, must be *perfectly clean* in this process, as in every other for negative purposes.

Several methods have been proposed by which the plate can be covered with a uniform film of albumen. Fortier recommends the use of a dropping tube capable of holding twice as much albumen as is required to cover the plate; this is filled about three-fourths full with the albumen by suction with the mouth, and then the upper aperture is closed with the first finger of the right hand. The plate, well cleaned, well dusted, and marked on the back with a diamond or with a small wafer, is inclined at an angle of not more than ten degrees with the horizon; breathe upon the plate, and then with the tube on the upper right hand corner allow the albumen to flow out; in the meanwhile carry the tube to the left side; then go back to

the right side, and proceed thus until three-fourths of the plate is covered: the quantity of albumen is supposed now to be sufficient, by a little management with a triangle of glass, to cover the whole plate.

Such a method as this, and many others quite similar to it, are sufficient to deter photographers from taking albumen pictures.

Another method, recommended by Couppier, consists in fixing on the back of the glass a long stem or handle of the thickness of a black lead pencil, with a cup-shaped cavity at the top, the sides are about a quarter of an inch in thickness, the whole having something of the appearance of an inverted hand bell. On the rim of the cup gutta-percha is melted. This gum can always be softened by heat when required for use, and when softened it is applied to the centre of the back of the plate by pressure. In this way the plate when cold adheres firmly to its handle. Noton's pneumatic holder, of course, is a superior substitute.

The plate is now flowed with albumen as you would with collodion; the greatest part of the surplus is taken off at the right-hand nearest corner; the albumen then is allowed to flow back to the left-hand farthest corner, and finally back to the middle. By a rotary motion communicated to the stem of the holder between the two hands, the collodion, affected by the centrifugal force, becomes uniformly distributed over the surface; and then, by a slight pressure of the thumb beneath the plate, the latter is removed from its connection with the stem, and put away to dry on a horizontal plane in a drying box or cupboard, to which dust can have the least access possible. If the plane be not horizontal, or if the glass be not uniform in thickness, the film of albumen will settle to the lowest points, and thus when dried will produce unequal action in the printing process. By this method the drying will not be effected in less than a day, during which time particles of dust may get admission and entirely spoil the plate.

The following is another method, modified from that of M. Ferrier:—

Supposing that stereoscopic negatives are required to be manipulated with:—Take a piece of brass about one-sixteenth of an inch in thickness, one quarter of an inch wider and longer than stereoscopic plates. Cut out all the interior portion, leaving only an outside skeleton half an inch wide. Turn up one-eighth of an inch so as to form a ledge, which will prevent the plate from falling out when once placed in this dish. Drill a hole in each corner of this ledge, or solder a ring at each corner on the outside. Be very particular that this skeleton dish lies horizontal when rested on a horizontal plate or board. To each ring attach a cord twelve inches in length, and bringing these cards together, tie them into a knot in such a careful manner that the brass dish, when suspended by the knot or by a ring in the knot, shall be also quite horizontal. It is evident by such a contrivance that a rotatory motion can easily be communicated to the plate by simply rotating the ring of suspension.

The plate is breathed upon and flowed with albumen; the surplus quantity is removed as before directed, and then the plate is placed upon the brass dish. Suspending the dish, a rotatory motion is communicated to it, and the film is made uniform. Previous to the operation of thus covering the glass, a plate of iron, about a foot square and supported on iron legs, is placed over an alcohol lamp or on one of the rings of a retort stand, and is made warm by the flame of the lamp. The suspended albumenized plate is brought right over the heated iron plate and rotated gently where there is a tendency in the albumen to accumulate unevenly. In a few minutes the plate will be dry and can be stowed away in a box with grooves for its reception. The excess of albumen is poured into a separate vessel, as it is not advisable to use it over again; nor is it advisable to use more than about three-fourths of the albumen after subsidence for a day or two; for the residuo at the bottom contains impurities that would detract from the perfection of the picture. The preparations of iodized albumen have to be used whilst fresh; consequently make it a business to coat as many glasses at a time as the albumen will cover for economy's sake.

Sensitizing the Film.

An oblong flat porcelain or glass dish is preferred to the vertical bath for the purpose of sensitizing the film; and if the dish be made twice as long as required it will answer the purpose best.

* This statement is scarcely correct. A sensitive collodion film containing iodide of silver only, if washed thoroughly and then exposed, will not yield an image without the addition of nitrate of silver to the developer. If this addition be made a picture is produced, but the exposure must be longer than for an un-washed plate. If the washed film contain bromide as well as iodide of silver, a faint image is developed without the addition of free nitrate.—ED. PHOTO NEWS.

Formula for Sensitizing Solution.

Nitrate of silver	1 ounce
Acetic acid	5 ounces
Distilled water	10 "
Iodide of potassium	2 grains.

Lay the albumen plate along one side of the glass dish, then raise this side and pour into the inclined side a sufficient quantity of the bath; with a dexterous move raise the inclined side so that the fluid may flow over the albumen film in one quick continuous layer. By this contrivance all lines or marks of stoppage are avoided. This is a very necessary provision here; for the slightest hesitation or stoppage will infallibly show its effect on the negative. About half a minute will be sufficient to *coagulate the albumen and to sensitize the film.* The operation is performed in the dark room. After sensitization the plate is removed from the bath by raising it first with a bent silver hook, and then seizing it by one corner with the hand. It is then washed under the tap, and left to soak in a dish of distilled water until the next plate is prepared.

The quantity of acetic acid in the above formula may be diminished in many instances; its object is to prevent fogging, but it diminishes sensitiveness at the same time. If with half the quantity no fogging supervenes, this quantity will be quite enough: in this manner, that is, beginning with a small amount of acetic acid, and gradually increasing until fogging ceases, more rapid effects may be obtained in the exposure. When the sensitized plates are kept long, they undergo a species of decomposition which induces fogging; the fresh plates, therefore, are in the best condition for producing normal effects with the greatest rapidity, because the sensitizing bath requires the least amount of acid.

Blisters are apt to arise in the film by immersion in the sensitizing bath, or during the subsequent operations. These are frequently owing to the imperfect cleaning of the plates, or in the clumsy flowing of the albumen. Gummy substances are sometimes added to the albumen in order to render it more adherent or less contractile.

The amount of exposure will depend on the conditions of light, the focal length of the lens, and the sensitiveness of the albumen. In the bright light of spring an exposure of two or three minutes with a pair of stereoscopic lenses will, in general, be amply sufficient. Experience alone can determine the amount of time required in a given case.

Development of the Image.

The plate is placed in a glass dish or in one of gutta percha, and the developer is poured upon it by the same mode of manipulation as just described to be used in the sensitizing operation.

Formula for the Developing Solution.

Gallic acid	8 grains.
Distilled water (90° Fah.)	2 ounces.

Previous to immersion in the above solution the plates are subjected to the softening action of a warm dilute solution of gallic acid (one grain to the oz. of distilled water), for half an hour. After this the plate is flowed with a sufficient quantity of the above solution containing five or six drops of a solution of nitrate of silver two per cent. strong. The image will soon begin to appear, and will proceed until the vigour of the print is satisfactory. The development is not so soon complete as in collodion operations, the time required varying from a few minutes to forty minutes or an hour. Almost any amount of exposure can be made to yield a good picture, by adapting the developing solution in accordance with the exposure. If the plate has been *under-exposed*, more silver will have to be used; if *over-exposed*, less will be found to be all that is necessary. Silver from the sensitizing bath might be used, but in this case it must contain more acetic acid. The weak solution above prescribed is to be preferred; and if there is a tendency to fogging, add a few drops of acetic acid to counteract the effect. As soon as the shades are sufficiently dense, the plate is removed from the bath, well washed in many waters, and then the image is fixed in a solution of hyposulphite of soda. No varnishing is required, because the albumen film is quite hard of itself.

ABOUT DRY PLATES.

BY J. MILTON SANDERS, M.D., LL.D.

ALTHOUGH much has been written upon the subject of dry plates, still it has not been exhausted, for the process has yet

to be discovered. The process I have followed for years I now describe, together with the recent improvements I have made. The collodion for this purpose must be prepared in the following manner:—In eight fluid ounces of alcohol, put eighty grains of gun cotton. Allow the cotton to remain in the fluid long enough to become thoroughly saturated, then you must pour on it eight fluid ounces of ether; shake, and the cotton will dissolve. Now add to it eighty grains of iodide of cadmium, and sixty grains of the bromide of the same metal, shake until the salts are dissolved and your collodion is finished. This collodion should remain standing in a shaded place for about a week, before it is fit for dry plates.

When ready to use, pour out one or two ounces of it in your collodion vial, and add sufficient tincture of iodine to it to change it to a dark brandy red; but the great body of the collodion should not be thus treated, or the iodine will deteriorate in a few days.

To prepare the dry plates proceed as follows:—Sensitize your plate with the above collodion in a fifty-grain bath, leaving it in the bath at least three minutes before you consider it thoroughly sensitized. Now take it out, hold it under the tap until all the nitrate of silver is washed off, and then pour upon it a filtered solution of twenty grains of tannic acid to the ounce of water.* I previously used a thin solution of albumen, but I find that tannic acid is fully as good, if not better.

Having poured off and on the tannic solution several times, drain the plate well, and place it away in your dark box.

Having placed the plate in your camera, give it about twice the length of exposure you would a wet plate. Return to your dark room, take the plate from the holder, and hold it under the tap until the tannic solution is washed off, and the collodion surface is thoroughly wetted. Now pour over it, or flow upon it, a fifty-grain solution of nitrate of silver, saturated with iodide of that metal † (or with some of your bath solution.) Drain it slightly, and develop with the following new developer:—

Water	20 ounces.
Sulphate of iron	1½ do.

Dissolve the iron, and with ammonia produce a slight precipitate in the solution. Then add—

Acetic acid, No. 8	2 ounces.
--------------------	-----	-----	-----	-----------

—Filter. ‡

Under this developer the picture will soon exhibit itself clear and intense; but if it should not come out sufficiently intense, intensify it further with bichloride of mercury, afterwards flowing upon it some diluted aqua ammonia to blacken the bichloride. I would mention that the developer given above will answer an admirable purpose for all wet plates. It brings out the picture beautifully clear and transparent, much more so than if the free sulphuric acid were allowed in the developer. I would further state that although I may be the first person to avail myself of this form of developer, that I was induced to do so through a suggestion of Professor Seely given in the April number of the *American Journal of Photography*.—*American Journal.*

St. Domingo, W. I., May, 1863.

THE ÆSTHETICS OF PORTRAITURE.

BY R. DISDREI.

(Continued from p. 332.)

The group portrait is often very much abused; and off all the different kinds of portraits, it is the one to which the very

* The tannic acid should be filtered in vacuo, if possible, for if exposed but a brief time to the air, a reaction takes place, oxygen is absorbed, carbonic acid given out, and gallic acid is formed. This latter acid will play the devil with your plate!

† We must caution our readers against following this suggestion. The iodide is not only useless, but mischievous.—*Ed. PHOTO. NEWS.*

‡ This solution must be used freshly made, as age soon deteriorates it.

§ A similar developer has been used in England for years, and repeatedly published.—*Ed. PHOTO. NEWS.*

worst attempts belong. If it is already so difficult to make a good likeness of a single person, how much more so must it be, to compose a scene in which, almost always, the individuals are of different age, sex, and character! Each member has his individual type, which must necessitate a particular choice of attitude, light, and expression. The painter is enabled to produce a certain unity by means of colour, modification of the form, and various other resources which his art places within his reach; but the photographer finds himself face to face with the reality, and must, of necessity, meet with obstacles which the most ingenious and complicated combinations of his art are powerless to overcome.

The method to which all the artists who have obtained the best portraits of this nature, have had recourse, consists in grouping and combining the different persons, as it were, by means of some action common to them all. It is thus that a mother is represented playing with her child; girls, admiring a piece of needlework; persons, examining an album of drawings, &c.

The photographer has taken advantage of every subject of this kind, and has almost invariably given some common employment or action to the persons which compose the group. We cannot but remark that some of these conceptions are weak and puerile. Our readers will naturally observe that an action should always be chosen that is calculated to represent the persons to advantage, without appearing improbable. The simpler this action is, the better for preserving to the picture the character of a portrait.

To make a portrait is, in fact, to represent an individual, and not an action; and, moreover, to represent him in a complete manner, he must be seen in his general and natural attitude, and not in the complicated and particular position you have placed him in. This observation is applicable with equal force to the representation of a single figure, as to that of a group. The action must be reserved for pictures, and scenes which are intended to represent a passion or a strong sentiment. But, for us, the subject is a portrait, and nothing more. The type, the bearing, and the character, constitute the interest, and this it is that we have to represent. It is in the works of the great masters that we must study the simple, yet grand, method of composing a portrait: Raphael, Titian, Vandyke, and Velasquez, have excelled in this. They have painted the men, and not merely their actions.

We have thus far spoken only of the dimensions and proportions of the model which are to be preserved and embellished in the portrait, regardless of the attitude chosen. We will now proceed to consider the pose of the figure.

The choice of position is extremely important, with regard to resemblance, and it is particularly in this that the artist must understand his model, and have a clear idea of the character of the person he wishes to represent.

The majority of photographers have two or three different positions to which they submit all their models, whether tall, short, long, or small. Moreover, nearly everybody, before having a photograph, studies and chooses an attitude beforehand, by the aid of a mirror, which, in many cases, is quite contrary to their natural bearing; a lady, for instance, of doubtful age, will take the free attitude of a young girl; a small, quiet-looking man, has an ambition to appear proud and bellicosus. The result of this is, that a great many portraits appear studied and stiff, of which the least fault is a perfect failure in resemblance, and generally in beauty.

The first condition of a good attitude is, that it should be in harmony with the age, stature, habits, and manners of the individual; secondly, that it should express the greatest beauty of which the model is susceptible. As we have already stated, the perfect knowledge of the individual is the sole guide for a suitable choice of the position; the defect to be most guarded against, is that caused by borrowed and studied attitudes. The photographer must, therefore, observe attentively, reflecting on his subject, and try, by all

possible means, to engage the attention of his model, and to endeavour to make him cease to think of the portrait for which he is come, seizing and noting the natural movements which are visible during these short intervals of forgetfulness.

The model, however, when seen in a natural manner, and perfectly free from any assumed bearing, will still present such a number of attitudes, that it would be very embarrassing to choose, if one had not already formed a clear idea as to the style in which the portrait should be represented. The model of which the character and type should be represented, in a serious and severe style, often present to the artist a number of accidental poses, which, although very natural in themselves, do not, however, give a complete idea of the person, and should, consequently, be rejected. It is the characteristic attitude that must be expressed, not one particular moment, but all the moments—the whole individual, in fact.

It is, moreover, necessary for the position to express unity of aspect, and that it be optically correct. One must, therefore, find a dominant movement which is in accord with all the other parts. The accessory movements, which present themselves naturally, fortify the unity of the figure, and render the aspect of it easy to seize. There will be a natural contrast of the principal lines, and one may invariably find means, in the disposition of the members, to bind these contrasts together by a series of accessory lines, which bring to mind, more or less, the principal ones. The dress, &c., is an important aid in attaining that harmony and unity of movement and form, which constitutes the optical beauty of the pose.

We have now to speak of physiognomy. As we have seen, it is not the real base of the resemblance, as is supposed by most photographers. It is, however, a very important condition, by means of the just proportion given to the face, with regard to the rest of the figure, and completes the harmony, beauty, and resemblance of the portrait.

The great difficulty here, as in the choice of attitude, is to distinguish from the multitude of different expressions presented by the model, the one which is most in accordance with the sentiment which is intended to be expressed by the "ensemble" of the portrait, and is at the same time the most favourable to a good resemblance. It is always the same law that should guide the artist; it is absolutely necessary that the just expression be visible through all the passing shades of the physiognomy; the fugitive movements of the head, the lip, the eyes; in short, that it should contain, and express, in itself, all the minor complementary details, and give the true character of the individual.

The artist must be strictly on his guard against borrowed and studied expressions, and act with much circumspection if he does not wish to run the risk of being deceived by the change. He will animate the face of the person by a varied conversation, noting in his mind the varied expressions; and, the moment arrived for taking the image on a sensitive plate, he will endeavour by all the means in his power to revive the one that he has chosen. This choice, therefore, requires a good deal of promptitude of observation and sure tact. This faculty is not given to all operators, nor even to the most able, and those who are endowed with the sentiment of the art. The changes are so rapid on the visage of the model, the shades so delicate and fugitive, as to elude the eye of the most skilful. It is not the wish of the operator that can give such and such an expression to the features, but the sentiment which animates and gives to the visage a corresponding expression to the sentiment awakened in the mind of the model. The artist will, therefore, seek, at the decisive moment, to revive the ideas which ought to give the model the expression that he has observed and chosen. How is he to succeed in this? is a very delicate question. The faculty of imitation is innate in man: sorrow and joy are contagious. If you observe a spectator at the theatre, you will see his physiognomy put itself in unison with that of the actor who interests

him; you will see the varied shades and changes of the scene pass over his countenance. The photographic artist has no other means of reviving the expression in the features of his model, than by taking the expression himself. He must, therefore, identify himself with the moral situation that he desires to create in the person to be represented, which is the only way of giving to his physiognomy the necessary expression for a perfect portrait. How often have we noticed the influence of the operator over the model? When some unexpected unpleasantness gives our face a cross expression, all the traits of our visage are reproduced in that of the model.

To obtain a good result, it is, before all, necessary that the artist be alone with the model. The least interruption with either will always compromise the success of the operation; this rule should be most strictly observed in the case of children. One should always avoid instructing them to smile, or to hold the head in such a manner, to be perfectly quiet, and all other such cautions as parents are in the habit of giving their children,—as when their minds are thus confused and preoccupied, it is almost impossible for the operator to obtain a faithful and pleasing pose. A child should be photographed without its being conscious of it.

The photographic atelier should always be separate from the laboratory, and perfectly removed from all noise, like that of the sculptor or painter.

It would be useless to enumerate all the false and disagreeable expressions of feature observable in so many portraits. We will however, notice a few of the most ordinary. In one, a smile has been attempted, and the model, according to the instructions of the photographer, has contracted the corners of his mouth, and thereby produced a grimace. In another, a tedious or tired expression replaces one of dignity or gravity. Such defects are caused by the artist not understanding his model, and being, therefore, unable to guide and direct him; in fact, he is wanting in either the practice or theory of his art. People are apt to think that the success often depends on the person to be represented, who will not submit to the wish of the operator, and persists in preserving some false or unfavourable expression. We would answer that the true artist would always find means of persuading his model to place himself under the necessary conditions. Moreover, he is never obliged to reproduce an absolutely obstinate model; and he should on no account become responsible for all the deformities that are presented to him.

DOINGS OF THE SUNBEAM.

[UNDER this title one of the most eloquent transatlantic writers, Oliver Wendell Holmes, gives, in the *Atlantic Monthly*, a picture of photography in the United States, commencing with a description of the establishment of Messrs. E. and H. T. Anthony, of New York. With one or two trifling excisions we reproduce the article.]

The guests of the neighbouring hotels, as they dally with their morning's omelet, little imagine what varied uses come out of the shells which furnished them their anticipatory repast of disappointed chickens. If they had visited Mr. Anthony's upper rooms, they would have seen a row of young women before certain broad, shallow pans, filled with the glairy albumen which once enveloped those potential fowls.

The one next us takes a large sheet of photographic paper (a paper made in Europe for this special purpose, very thin, smooth, and compact), and floats it evenly on the surface of the albumen. Presently she lifts it very carefully by the turned-up corners and hangs it *bias*, as a seamstress might say, that is, cornerwise, on a string, to dry. This "albumenized" paper is sold most extensively to photographers, who find it cheaper to buy than to prepare it. It keeps for a long time uninjured, and is "sensitized" when wanted, as we shall see by-and-by.

The amount of photographic paper which is annually imported from France and Germany has been estimated at fifteen thousand reams. Ten thousand native partlets—

"Sic vos non vobis iudicatis, ares"—

cackle over the promise of their inchoate offspring, doomed to perish unfeathered, before fate has decided whether they shall cluck or crow, for the sole use of the minions of the sun and the feeders of the caravanseras.

In another portion of the same establishment are great collections of the chemical substances used in photography. To give an idea of the scale on which these are required, we may state that the estimate of the annual consumption of the precious metals for photographic purposes, in this country, is set down at ten tons for silver, and half a ton for gold. Vast quantities of the hyposulphite of soda, which, we shall see, plays an important part in the process of preparing the negative plate, and finishing the positive print, are also demanded.

In another building, provided with steam-power, which performs much of the labour, is carried on the great work of manufacturing photographic albums, cases for portraits, parts of cameras, and of printing pictures from negatives. Many of these branches of work are very interesting. The luxurious album, embossed, clasped, gilded, resplendent as a tropical butterfly, goes through as many transformations as a "purple emperor." It begins a pasteboard larva, is swathed and pressed and glued into the condition of a chrysalis, and at last alights on the centre-table gorgeous in gold and velvet, the perfect *imago*. The cases for portraits are made in lengths, and cut up, somewhat as, they say, ships are built in Maine, a mile at a time, to be afterwards sawed across, so as to become sloops, schooners, or such other sized craft as may happen to be wanted.

Each single process in the manufacture of elaborate products of skill oftentimes seems, and is, very simple. The workmen in large establishments, where labour is greatly subdivided, become wonderfully adroit in doing a fraction of something. They always remind us of the Chinese or the old Egyptians. A young person who mounts photographs on cards all day long confessed to having never, or almost never, seen a negative developed, though standing at the time within a few feet of the dark closet where the process was going on all day long. One forlorn individual will, perhaps, pass his days in the single work of cleaning the glass plates for negatives. Almost at his elbow is a toning bath, but he would think it a good joke, if you asked him whether a picture had lain long enough in the solution of gold or hyposulphite.

We left the great manufacturing establishment of the Messrs. Anthony more than ever impressed with the vast accession of happiness which has come to mankind through this art, which has spread itself as widely as civilization. The photographer can procure every article needed for his work at moderate cost, and in quantities suited to his wants. His prices have, consequently, come down to such a point that pauperism itself need hardly shrink from the outlay required for a family portrait-gallery. The "tin-types," as the small miniatures are called—stannotypes would be the proper name—are furnished at the rate of *two cents* each! A portrait such as Isabell could not paint for a marshal of France—a likeness such as Malbone could not make of a President's lady—to be had for two coppers—a dozen *chefs d'œuvre* for a quarter of a dollar!

We had been for a long time meditating a devotion of a part of what is left of our more or less youthful energies to acquiring practical knowledge of the photographic art. The auspicious moment came at last, and we entered ourselves as the temporary apprentice of Mr. J. W. Black, of this city, well known as a most skilful photographer, and friendly assistant of beginners in the art.

We consider ourselves at this present time competent to set up a photographic ambulance, or to hang out a sign in any modest country town. We should, no doubt, over-time and under-tone, and otherwise wring the countenances of some of our sitters; but we should get the knack in a week or two, and if Baron Wenzel owned to having spoiled a hat-full of eyes before he had fairly learned how to operate for cataract, we need not think too much of libelling a few village physiognomies before considering ourselves fit to take the minister and his deacons. After years of practice there is always something to learn, but every one is surprised to find how little time is required for the acquisition of skill enough to make a passable negative, and print a tolerable picture. We could not help learning, with the aid that was afforded us by Mr. Black and his assistants, who were all so very courteous and pleasant, that, as a token of gratitude, we offered to take photographs of any of them who would sit to us for that purpose. Every stage of the process, from preparing a plato

to mounting a finished sun-print, we have taught our hands to perform, and can therefore speak with a certain authority to those who wish to learn the way of working with the sun-beam.

Notwithstanding the fact that the process of making a photographic picture is detailed in a great many books, nay, although we have given a brief account of the principal stages of it in one of our former articles, we are going to take the reader into the sanctuary of the art with us, and ask him to assist, in the French sense of the word, while we make a photograph—say, rather, while the mysterious forces which we place in condition to act work that miracle for us.

We are in a room lighted through a roof of ground glass, its walls covered with blue paper to avoid reflection. A camera mounted on an adjustable stand is before us. We will fasten this picture, which we are going to copy, against the wall. Now we place the camera opposite to it, and bring it into focus so as to give a clear image on the square of ground glass in the interior of the instrument. If the image is too large, we push the camera back; if too small, push it up towards the picture and focus again. The image is wrong side up, as we see; but if we take the trouble to reverse the picture we are copying, it will appear in its proper position in the camera. Having got an image of the right size, and perfectly sharp, we will prepare a sensitive plate, which shall be placed exactly where the ground glass now is, so that this same image shall be printed on it.

For this purpose we must quit the warm precincts of the cheerful day, and go into the narrow den where the deeds of darkness are done. Its dimensions are of the smallest, and its aspect of the rudest. A feeble yellow flame from a gas-light is all that illuminates it. All round us are troughs and bottles, and water-pipes, and ill-conditioned utensils of various kinds. Everything is blackened with nitrate of silver; every form of spot, of streak, of splash, of spatter, of stain, is to be seen upon the floor, the walls, the shelves, the vessels. Leave all linen behind you, ye who enter here, or at least protect it at every exposed point. Cover your hands in gauntlets of india-rubber, if you would not utter Lady Macbeth's soliloquy over them when they come to the light of day. Defend the nether garments with overalls, such as plain artisans are wont to wear. Button the ancient coat over the candid shirt-front, and hold up the retracted wristbands by elastic bands around the shirt-sleeve above the elbow. Conscience and nitrate of silver are tell-tales that never forget any tampering with them, and the broader the light the darker their record. Now to our work.

(To be continued.)

Correspondence.

PHOTOGRAPHIC REPRODUCTION OF PICTURES.

SIR,—Do you not think that much of the bitterness of feeling between publishers of engravings on one hand, and certain unscrupulous photographers, on the other, might be avoided, and the growing taste of the general public for art fostered and encouraged by the plan I now propose for publishing the works of the celebrated artists of the present day. Suppose one or two, or more, of the leading photographers were to commission one of our best artists to paint an original work in monochrome, with the express understanding that it was to be copied by photography. When the work was finished the London firm could take negatives of the painting, and sell them to photographers in the country, who would agree to sell the prints, of a certain fixed size and at a fixed price. How much better and straightforward this would be than the miserable, sneaking way, of copying engravings, and running all the risk of the pains and penalties attached thereto. Again, how faithfully photography would convey the imprint of the artist's mind, even to the very touch and manner of the painter.

As one instance of the value of photography in reproducing the work of the artist, look at the woodcut in the

Illustrated London News, of the painting of Caesar leaving the palace after the burning of Rome,* and look at the photograph of the same by the London Stereoscopic Company. The former gives no idea of the distance—the latter gives it in its most perfect form. So far as I have seen, all engravings seem deficient in this respect, from a woodcut in a newspaper to a fine line engraving; the effect of distance does not seem to me to be rendered near so truly as by a good painting or photograph. Of course, this case is an extreme one, and not a fair comparison; still, it may serve, as being so familiar to many of your readers.—Yours, truly,

THOS. GULLIVER.

Union Street, Swansea.

Photographic Notes and Queries.

WEAK PRINTING, BATHS.

SIR,—Under the above heading, one of your correspondents, who adopted the *nom de plume* of "Publicolo," published in your *News*, of the 24th of April last, a recipe as follows—silver 20 grains, nitrate of soda 60 grains, to 1 ounce of water. From the day I received your journal of that date up to the present, I have used no other bath for my papers. I have never had a mealy picture, and but once have had occasion to clean my bath with kaolin. I have used about a dozen 5 by 4 papers daily, and beg to enclose you a specimen. Amongst the many excellent suggestions published in your columns, none have been more valuable in a monetary sense than the above.—Yours obediently,

AN AMATEUR.

[The print received is a brilliant, well toned print, quite free from mealiness.—ED.]

ON CERTAIN STATES OF THE ATMOSPHERE WITH RESPECT TO ACTINISM.

SIR,—In reply to Mr. Warner's question as to the amount of actinism during the early part of this month, permit me to state that I was taking *carte de visite* portraits here (about twenty miles north of Ross), on the 6th, 7th, and 8th of July, and my experience was quite the reverse of his. I never met with finer weather for the purpose, having obtained negative after negative in the open air, showing no trace of under exposure in the details of foliage in the background, with exposures of from one and a half to two seconds. Amon. sulph. of iron developer, and in most cases only one application, no intensifying being required. The collodion, Home and Thornthwaite's new bromo-iodized, of which I can speak quite as highly as Mr. Warner does; the lens, an excellent C. de V., by Mr. Cox; the bath, an old one intended for the Pothergill process, and not intended for very rapid work.

I may, perhaps, take this opportunity of mentioning a circumstance of the kind alluded to by Mr. Warner, which happened to myself last autumn. Some friends had appointed to come here on a certain afternoon to be photographed for a relative in India. Being desirous of producing a good result I took all the usual precautions, carefully preparing fresh developing solutions, testing the bath, &c. About mid-day the weather began to get rather dull, yet I thought longer exposure would enable us to take good pictures. However, on trial I found that no exposure, however long (and at last I gave exposures with the full aperture of a portrait combination, which would have been considered long with a landscape lens and small stop), would produce anything beyond the faintest trace of a positive. We were obliged to give it up after several trials, and I took the precaution of setting aside the bath and remaining developer for trial next afternoon, at the same hour, when everything went well, and good negatives were obtained with the same collodion and chemicals which had failed so utterly the day before.

On examining the atmosphere after our defeat, I fancied that I could detect amongst the trees a very thin, faint haze, of a peculiar greenish yellow hue, such as I have never seen before or since; but, imagination is apt to play one tricks on such occasions, and I shall be glad to learn whether any one else has noticed the appearance I mention.

It would be well if all photographers who experience this mysterious phenomenon, would publish an account of the occurrence in one of the journals; several instances are already

* Shown in the International Exhibition.

before the public, the first, unless I mistake, being described incidentally in a paper by Mr. Rejlander before the Photographic Society of London some years back. Comparison of numerous independent observations might lead to most interesting and unexpected results. At present we have too little to base theories upon, all we can do is to observe, and record faithfully what we see.—I am, Sir, yours most truly, ROBERT DOUGLAS.

Stoke Laey Rectory, Bromyard, July 14th, 1863.

DEAR SIR,—In last week's NEWS I saw a letter from Mr. Warner, respecting the non-actinic weather lately. Curious enough, when the NEWS came to hand, I was just about writing to you on the subject; as, during the past week or ten days, I had experienced in a marked degree all that Mr. Warner complains of.

I found that I had to give nearly four times as long exposures as I usually do, for the wet process, tannin, and Dr. Norris's plates, and also for chloridized paper. I also noticed that albumenized paper decomposed much more rapidly than usual after being sensitized.

The want of actinism in the light might be accounted for on some of the days referred to by the absence of clouds—but, clouds or no clouds, it seemed very nearly the same.—I am, yours truly,

H. COOPER, JUN.

[We have had verbal communications from photographers of eminence, noticing the same phenomenon. The extreme dryness of the atmosphere appears to be generally regarded as the cause. The rapid decomposition or discolouration of excited paper is a singular concomitant, of which also we have had several complaints. Dryness would generally retard this, but we presume the extreme heat has acted even in the absence of moisture.—ED.]

DEAR SIR,—Having read Mr. Warner's remarks upon non-actinic weather, in the NEWS of the 10th instant, and being one of your numerous readers, my reply to that gentleman's inquiries is at your service.

I have experienced the same inconvenience from the peculiarities in the state of the atmosphere at Ipswich of which he writes.

It occurred immediately after a very severe thunder-storm which took place on the night of the 24th of June, and has continued until this morning when the usual actinic power seemed to return, and has continued throughout the day with excellent results.

It appears to me that Mr. W.'s idea of a want of electricity in the atmosphere is a correct one, and quite sufficient to account for many troubles and perplexities to which photographers are subject.—I am, dear sir, yours truly,

J. STOKES.

SIR,—I can fully bear out Mr. Warner's statements regarding the present want of actinism. Indeed, on several occasions during the last three weeks, I have found it all but impossible to get a picture. Yesterday, at 6.30 p.m., I took a negative with an exposure of 15 seconds, but in the middle of the day I had to expose for 25 or 30 seconds, and even that was scarcely sufficient. I am quite unable to account for the change, as the sky was bright and cloudless the whole day.

I ought to mention that I used the same collodion, developer, &c., as well as the same sized stop. In the middle of the day the negatives required a great deal of intensifying, but the one taken in the evening came up strong and brilliant with iron only. On all the negatives I have observed a very peculiar deposit; by reflected light the shadows seem quite buried, but by transmitted light they are quite clear, and the deposit does not seem in any way to affect the printing qualities of the negative. Unless my experiments mislead me, there is at present in the atmosphere much less than the normal quantity of ozone. Might not that be the cause of our difficulties?—I remain, yours truly,

JAMES MUNRO.

DEAR SIR,—Allow me to inform Mr. Warner that my experience of the photographic influence of the atmosphere here has corresponded generally with his, with the exception of a day or two. There has been at times heavy fogs arising suddenly; and, on some days, the evening has closed sooner than usual, although the weather was fine. I think I remember to have read, that in some countries when the sun produces great heat, and the atmosphere is very dry, that exposures are required to be much lengthened, compared with those required in this

country in general; may not the decreased density, or the absorption of gases drawn from the earth so alter the quality of the atmosphere as to greatly reduce its actinic properties? Sick headaches, and pains in the head have been prevalent, which will be accounted for by the great heat causing a too sudden increase of the circulation of the blood to the brain; care should be taken to avoid exposure to the sun's rays during the middle of the day.—I am, dear Sir, yours truly,

T. MARTIN.

PHOTO-ZINCOGRAPHY AND PHOTO-PAPYROGRAPHY.—A correspondent of the *Athenæum* writes:—"It is curious to note, whenever the properties of any substance (if light can be so designated) have been discovered, and the students of the science are intent upon multiplying the variety of its applications, how by apparent accident, and sometimes coincidentally, the phenomena of a new art are suggested to persons widely sundered by place and circumstances. Colonel Sir Henry James, at Southampton, and Mr. Osborne, at the antipodes (Melbourne), hit upon the zincograph in the same month: the latter obtaining for his invention a patent, with a reward of £1,000 from the spirited and munificent Government of Victoria; Colonel James and his accomplished subordinate, Captain A. De C. Scott, resting content under the conscious sense of public usefulness with the honour conferred by the noble and enlightened of all lands. In December, 1859, an ingenious young lady asks Sir Henry how she could get her etchings cheaply printed; and he takes one of them to the Ordnance Office, at Southampton, submits it to the chromo-carbon process, and transfers the imprint to the zinc plate. This was the first zincograph. Again, shortly afterwards, one of the workmen having, by mistake, laid the ink on the wrong side of the paper, thus giving a reversed outline, Sir Henry obtains from this negative on paper a copy of the original, and ascertains that the negative can be printed on paper instead of glass. Here was the first papyrograph. Now, by these discoveries, we possess the means of reproducing, with a fidelity, cheapness, and durability hitherto unattained, copies of any subject, unaltered, enlarged, or reduced in size, and with every gradation of shade or tone; for the lithographic ink used, of which the main ingredient is pure carbon, is, like the carbonized ink of some of the ancient palimpsests, ineffaceable, except by the destruction of the material on which it is inscribed. In the reduction of plans and maps the greatest deviation by the photographic process did not amount to 1-400th part of an inch in the rectangle; and even this minute error is not cumulative, and can be estimated with mathematical accuracy, if required. With deeds, MSS., and all artistic and natural objects, so minute a deviation would, even if appreciable, be of no consequence. It would not be admissible to detail here the modes and manipulation of these novel appliances of photography, which afford to all the learned professions, as well as the workers in every employment, useful and ornamental, advantages as widely diffused as the very light which is their intervenient instrument; but the manipulation is not so difficult, nor the materials so expensive, as to prevent the practice of photo-zincography and photo-papyrography, even by lady amateurs, who would wish to furnish their drawing-rooms with fac-similes of objects of rare beauty and elegance, whether the originals be the productions of their own talent, or gathered from the kingdoms of Nature and of Art."

[Referring to this paragraph, Mr. Osborne wrote the following letter to the editor of the *Athenæum*. No notice having been taken of his communication, he requests us to publish it.]

SIR,—May I be permitted to correct an erroneous statement respecting my photolithographic process which appeared in the *Athenæum* of 6th of June?

In a communication signed John Locke, it is clearly and deliberately asserted that I invented my process in Melbourne in the same month as Colonel Sir Henry James initiated his method at Southampton. This is very far from being the case, mine being several months antecedent to Sir Henry's process, as it dates from the 19th of August, 1859, and the publication of maps by it commenced at the Department of Lands and Survey on the 3rd of September following. Bearing in mind the circumstances under which my invention was made, I attach considerable importance to my hitherto undisputed priority, and trust you will favour me by giving publicity to these few words in explanation of the present mistake.—Yours obediently,

J. W. OSBORNE.

67, Potsdamer St. Berlin, 13th June, 1863.

Talk in the Studio.

TRANSFERRING FILMS.—A valued correspondent, Mr. T. Barrett, says:—"I think the great objection to the method of transferring the collodion film to paper, described in the last number of the NEWS, is this, that the printing must be through the paper, which must materially diminish the sharpness of the print. Now, the method of transfer which I described a long time back, is free from this objection, as the film, being removed from the glass by means of gutta-percha dissolved in benzole, is attached to the paper on the same side that was next the glass. The process is very easy and simple."

SOUTH LONDON PHOTOGRAPHIC SOCIETY'S ANNUAL DINNER.—The members of the South London Photographic Society dined together on Saturday last, at the "Eagle," Snaresbrook, Epping Forest. They enjoyed an excellent dinner, made speeches, and drank toasts, but did not discover the source of the photographic Nile. We need not, therefore, enter into further details of the meeting.

To Correspondents.

METRIC.—All that we can say with certainty of the two transferred films is that they are fogged. Whether this be due to the condition of the bath, exposure to diffused light, or the use of a hot developer is uncertain. We should be much disposed to attribute it to the latter cause. A hot developer is not suited to plates containing any free nitrate, as those by Mr. Keene's process do. 2. The mottled effect in the print is due to imperfect fixation, arising from the use of an old or weak solution of hyposulphite, or too short immersion. 3. Of the samples of glass enclosed No. 4 is best suited for a dark-room, as it cuts off all the blue and a large portion of the green rays.

AMATEUR IN ST. THOMAS, W. I.—There is no work published on the manufacture of photographic chemicals, nor can we recommend you to any work on manufacturing chemistry of an extremely simple character. The articles on "Photographic Chemicals," at present in progress in our pages, were undertaken to supply the want you express, and you will probably obtain all the information you require, either from the articles already published or those which will in due course appear. "Gmelin's Chemistry" is one of the best works for general reference.

AN OLD SUB.—Creosote and benzole are essentially different bodies both in their properties and origin, although they possess some analogies in both. Creosote is a preparation obtained by a complicated process from wood-tar, and is most remarkable for its antiseptic properties. Benzole is obtained by the distillation of coal-tar, and is a valuable solvent for gutta-percha, india-rubber, and various resins. Kerosene is a preparation recently introduced of a similar character, and is, we believe, obtained by distillation from wood-tar.

MEALINESS.—Some varieties of paper are more disposed to the production of mealiness than others, but in the examples sent we fancy the negatives are chiefly chargeable. The old print sent to show absence of mealiness is decidedly mealy; but being from a bright negative it does not show the fault in an offensive degree. The print sent as being mealy is apparently from a less brilliant negative, and is not sufficiently printed. When the tendency to mealiness is present use the toning bath weaker and older; this is the best remedy we know. We will endeavour to try the piece of paper sent when occasion serves. See Mr. Parkinson's toning formula in the present number; but remember that we in no case counsel the use of a lime bath until it is a few days old.

N. G.—The cause of the yellowness in your print is imperfect fixation. The hypo bath is too weak, too old, the print has not been in a sufficient length of time, or it has been stuck to another, and so has not been sufficiently acted upon by the solution.

DUNCAN.—The "frosted" effect of which you speak in many stereoscopic slides arises from slight under-exposure and over-development in the negative. The result is an excess of vigour trenching upon hardness, which, whilst it only appears to give brilliancy to the print, when examined as a picture on a flat surface, appears snowy in the stereoscope. Very soft prints full of detail are best for stereoscopic effects, and many pictures which appear tame, flat, and wanting in force out of the stereoscope, are quite perfect when examined by its aid.

D. SMITH.—The black spots to which you refer might arise from a variety of causes, but without an example of the especial kind of spot, we cannot offer suggestions as to the cause, without occupying too much space. It is certainly desirable to have the developing room, the table, &c., free from any kind of loose particles, which might come in contact with the negative in any stage of its production. In exposing your bath you do not state whether you neutralized it first. The best plan is to proceed as follows: first neutralize the bath by adding a solution of bicarbonate of soda cautiously, a little at a time, until there is a slight permanent precipitate. If it have been giving pin-holes in the negatives, it is probable that it is supersaturated with iodide, to get rid of which dilute the solution with its own bulk of distilled water, which will make it turbid, or milky, by the precipitation of iodide. Now, expose the whole for a few hours to a bright sun; then filter out the black precipitate, add sufficient nitrate of silver to make up the strength, and try a plate. If there be any trace of fogging, add a drop or two of nitric acid. As we cannot with certainty follow the history of your bath through all its stages, we have repeated the proper steps to be taken. Never add ammonia to your negative bath, it will introduce you to many troubles. The collodion of which you speak as very tender has proved in our hands very tough and adherent. 2. With regard to the printing bath, there are several efficient means of removing the colour. Kaolin may be used; we prefer the use of a little of a solution of common salt. That does, as you remark, precipi-

tate a little silver as chloride, but it takes down with it the colouring matter at the same time. 3. The silver bath into which glue was dropped may be purified by neutralizing and sunning, and so with the other to which you refer; sometimes a long sunning is necessary to precipitate all foreign matter present. 4. The mottled effect of the prints received is due to mealiness. Use a weaker and older toning bath. The prints are not sharp. Your lens is in fault, or it is not focussed carefully.

A FINE WEATHER TOURIST.—Where rapidity is unimportant, and good keeping qualities imperative, the best dry processes are the collodio-albumen and the tannin. If simplicity of preparation be an object the latter is preferable; but if the best, most certain results, without reference to trouble, be the consideration, then we should prefer the collodio-albumen. 2. The tannin process, as employed by Mr. Hurst, is, we believe, so far as the preparation of the plates is concerned, the tannin process in its simplicity as originally propounded: plates with preliminary coating of gelatine; coated with a bromo-iodized collodion; excited in slightly acid bath; well washed; and coated with 15-grain solution of tannin. His mode of securing rapidity is by a modification of the developer which we are not at present at liberty to publish.

A SUBSCRIBER.—Plates prepared by the honey process ought not to be immersed in the nitrate bath before development, but simply moistened with distilled water. We cannot speak of the respective merits of the samples of bromo-iodized collodion to which you refer; but think it very probable that any of them would answer. The spots to which you refer as occurring on honey plates most likely arise from dust having settled on the tacky surface.

A LADY OPERATOR.—If you use India-rubber finger-stalls to protect the fingers from stains whilst developing, take care not to let them come into contact with hypo, as that would probably cause a stain on developing the next plate. It is well to keep the finger stalls for development only; but if you use them whilst performing other operations make it a point to frequently rinse them.

M. A. P.—It is very probable that if you announce the business for sale in our advertising columns, you will meet with various applicants to purchase. The value of the business will necessarily depend upon many circumstances, and especially on the annual amount of profit realized. From your description it is a property which will find ready sale.

THOMAS KIRBY.—In neutralizing the free hydrochloric acid in making your chloride of gold, the addition of bicarbonate of soda produces chloride of sodium, which is not injurious. But it is a somewhat critical operation, as the slightest excess is apt to produce decomposition, and a precipitate of metallic gold. It is better to drive off the acid by gentle heat, and neutralize any trace left when making the toning bath. 2. The method you employ to prevent the varnish dissolving the film is practically, we imagine, weakening the alcohol: the spirit with which the varnish is made is probably nearly absolute. A portion of this you evaporate, and then add ordinary alcohol, which is much weaker.

ANTHRA SUBSCRIBER.—It is probable that the paper may have been prepared with stale albumen, which would make it more readily decompose, when silvered, in warm weather; or it may have had acetic acid added to the albumen, and this is often a source of rapid discolouration. A trace of nitric acid in the silver bath will aid the paper in preserving its colour. After exciting, keep the paper in a dry, cool place, and that will aid you a little.

P.—You may rest perfectly satisfied that the pursuit of photography, either amateur or professional, is in every way honourable. You will commence with the wet collodion process, of course, and then, if you require it for landscape purposes, give your attention to a dry process. The mentioned supplies cameras, we believe, of excellent quality.

J. GILBERT.—The reason of your acid dissolving the cotton at a temperature of 150° is, that the nitric acid is too weak. Your remedy, if you continue to use the same nitric acid, is to add a larger proportion of sulphuric acid. 2. You will find the method of purifying silver from copper stated at length in the early part of Vol. V. of the PHOTOGRAPHIC NEWS, the Nos. for January 4 and 18, 1861. We are by no means certain that the presence of nitrate of copper in minute traces is detrimental. The manufacture of chloride of gold is very simple: dissolve pure gold in aqua-regia (nitric acid one part, hydrochloric acid two parts), and then evaporate the acids by gentle heat.

A SUBSCRIBER.—The printing of the card received is very good, but the negative is hard. If you can guarantee your employer always equally good prints, you will, probably, find employment as a printer. You are the third correspondent we have to answer this week with the simple signature of "A Subscriber." It is better to use a name more distinctive.

THOMAS BARRETT.—We apprehend that it must have been due to some peculiarity in the collodion which caused it to give crispness on the addition of amber, after Jeanrenaud's formula. We have not had an opportunity of showing the specimen yet. We print your remark on transferring in another column.

NON-ACTING WEATHER.—Mr. W. H. WARNER, of Ross, presents his compliments to the readers of the NEWS, and would feel obliged by their communicating with him direct on any further details on the matter contained in his letter of last week on the above subject. Several correspondents in our next.

PHOTOGRAPHY IN PARIS.

PORTRAITURE.

It has often been remarked—indeed, it has become a generally recognized fact, that the French photographers especially excel in the delineation of the human figure, in all kinds of portraiture. We find all kinds of portraits, from the *carte de visite* to the full length life size, executed equally well. Delicacy, roundness, softness, and vigour characterize most of their photography. Ease and grace are common in the positions, and, with some few exceptions, the accessories and general arrangement of the sitter are spirited and effective, without being theatrical. There is a greater variety of style and effect, and less of the commonplace, than we find in this country. The examination of many portraits, either in an exhibition or in the atelier of an artist, generally becomes tedious, if prolonged. But, in Paris, the variety of style, size, subject, and treatment keeps alive the interest satisfactorily.

In the exhibition, for instance, one artist shows chiefly fine card portraits, with great variety of treatment. Another exhibits a frame of exquisite vignette heads, of 5 by 4 plates. Then we have the life-size busts of Alophe, taken direct, without enlargement. These are not to our taste, but still they are wonderfully bold and round, and, considering the method, wonderfully free from coarseness. There appears to be some degree of mystery as to the method of producing these. They are styled untouched, and taken direct, but it is said that the negatives are much worked upon by M. Alophe, who was a painter before he became photographer. It must be remembered, however, that in working upon a negative, lights only can be put in—it would be impossible to increase the depth of shadows. The density of some parts may be increased by pigment, but not decreased. Be this as it may, the pictures are marvellously effective, but to us not so pleasing as a good solar camera enlargement. Next we find a screen of most excellent photographs on whole plates, in which each portrait is surrounded by a singular *entourage*, in the shape of a photographic frame, forming part of the picture. The sitter has been practically framed, or placed in a very rich and elaborately designed picture frame, through which he looks. The effect is singular and striking, but scarcely artistic. The photography is very exquisite, especially round, soft, and well modelled, and the positions are good. Were it not that all is so well done we fear the effect of this *entourage* to the figure would be vulgar. We have next the spirited whole-plate and ten by eight portraits, by Adam Solomon, sculptor and photographer; and pictures of the same class, by Pierre Petit, all fine studies of pose and excellent specimens of photography, but many of them spoiled by unnecessary touching. Numa Blanc adds to the interest of his fine portraits by stating that the enlargements were effected by aid of the electric light, by which also, by the way, Nadar's photographs of the catacombs were obtained. Other distinctive characteristics giving interest to the portraits might be mentioned, but it is not necessary to enlarge further.

Amongst the first, perhaps *the* first, portrait establishments in Paris, is that of M. Disderi. A brief sketch of what we observed there may be interesting to our readers. One of the most noticeable features of the establishment was the number and excellence of the solar camera enlargements, of every size and style, from the bust half life size to the full-length standing figure of the real proportions of nature; from the simple untouched photograph, to the most elaborately-finished oil painting. All the enlargements appeared to be exceedingly perfect, those untouched as well as the most highly finished. There was an absence of the coarse black and white effect, without modelling, which we have seen in many solar camera pictures; and an equal absence of the feeble, flat, grey, ill-defined pictures which other artists produce with the same instrument. A full-length life-size of an officer in uniform appeared to us almost perfect, and so far as we could judge, untouched. The handsome suite of reception rooms was crowded with excellent specimens of art and photography, produced by the aid of the solar camera. The enlargements, we were informed, are not effected in Paris, but in Toulon, where M. Disderi has an establishment for this and similar work in which a pure and actinic light is of great importance, the ordinary printing establishment being in the immediate neighbourhood of Paris, at St. Cloud, if we remember aright.

Ascending to the ateliers, M. Lacan again kindly officiating as *eiccone*, we find M. Disderi actively engaged in the posing and arrangement of sitters. The glass-room is large and spacious, having top light and side light, all front light being carefully cut off. The space not immediately in use is filled with a large profusion of accessories, well designed articles of furniture, and toys to attract the attention of children. M. Disderi's management of the sitter is an admirable embodiment of the principles he lays down in the valuable and interesting article on the "Aesthetics of Portraiture," which is concluded in the present number of the PHOTOGRAPHIC NEWS. The general arrangement of background and accessories having been secured, M. Disderi places himself in the position he desires his model to assume. The sitter does his best to imitate the position, and if he fail, his awkwardness is pointed out to him with good-humoured raillery, sometimes accompanied by pantomime, illustrating the awkward effect produced. There is no attempt to twist the head, body, or limbs into the desired position; but the sitter is requested to move away, and then begin *de novo*. There is little danger, therefore, of the twisted, stiff, anxious look too often seen in photographic portraits. The effect of placing the sitter in position, and attempting to get the right view by a series of little modifications requiring a few minutes to make, generally results in great fatigue to the sitter, and an utter want of grace or ease in the picture. M. Disderi's aim appears to be to avoid producing fatigue, anxiety, and depression in the sitter, and in this he seems very successful. His operations in arrangement are, moreover, exceedingly rapid, which materially adds in preventing fatigue to the sitter. Three negatives for

which, at his request, we stood, only occupied about as many minutes, although the exposure was fourteen seconds.

The lens employed was a French one of about twelve inches focus. The distance of the sitter for card portraits, full-length figures was, so far as we could measure by the eye, about thirty feet. We may here remark, however, that a custom is beginning to prevail in Paris of avoiding full-length figures in portraits of gentlemen. Instead of the full-length, about three-quarters of the figure are given, the great difficulty of arranging, with pictorial effect, the trousered legs of the male figure is thus avoided. The distance for these sizes was about twenty feet. One lens only was used, but the plates were twelve by ten, and contained eight on one plate. To English photographers it will probably appear odd that plates of this size should be used whilst two or three negatives only of each sitter are taken, several different persons being thus taken on one plate. Notwithstanding the celerity of the operations, it must often happen that the arrangement and posing of two or three different persons, must occupy a space of from twenty minutes to half an hour, during which time the sensitive plate, in very hot weather, apparently keeps in good condition, as we saw no signs of stains or other bad results.

Entering the dark room, another circumstance strikes us as novel to English photographers: the nitrate bath is not upright, but a large flat dish. The solution is tilted to one end, and the plate placed, face upwards, on the bottom of the dish, which is then lowered into the horizontal position, and the solution brought in an even wave over its face. After standing a few seconds the dish is well rocked, so as to equalize the action, and prevent the settlement of any loose particles of dust, &c., from becoming attached to the film.

The collodion is freely bromized, more so, however, in winter than in summer. The silver bath for summer use is about thirty grains to the ounce, or six per cent. In winter it is used stronger. The developing solution used contains twenty grains of protosulphate of iron, and twenty minims of acetic acid to the ounce of water. The negative produced by these solutions give a tolerably vigorous image with the iron alone; but when further intensifying is required it is effected by an application of the same iron solution, to which a few drops of a fifteen-grain silver solution is added. M. Disderi informed us, referring to the developer, that he had never used pyrogallic acid for development at all, having employed iron from his first trial of the collodion process. The negatives we saw were all clean, brilliant, soft and well modelled, possessing, in fact, those qualities which have made the name of Disderi celebrated all over the world.

Scientific Gossip.

WHITE LEAD AND ZINC WHITE—IS ANYTHING OPAQUE?—LIGHT ONLY EXISTS IN THE EYE.

EVERY artist who has been troubled with the rapid sulphuration of white lead, and has been obliged to resort to the employment of zinc white in order to prevent the high lights of his painting from gradually darkening, has noticed that whilst equally white in appearance the white lead possesses considerably more *body* than the zinc white. Whence arises this difference? What is the meaning of the term *body* as applied to pigments? How is it that of two powders, apparently equal in their colour and brilliancy, one looks feeble and transparent when employed as a paint, whilst the other shines out with redoubled vigour? Such questions as these cannot fail to have suggested themselves to many persons, and have elicited a variety of answers. Mr. Barnard S. Proctor has lately made these and other similar questions the text for some very interesting as well as philosophical reflections upon some phenomena of light which have struck us as being so valuable, both on account of the recondite facts they deal with and the popular way in which they are

discussed, that we are induced to give a brief outline of them to our readers. "As white as fine linen, flour, chalk," "as white as snow," are frequent comparisons, but they are all dull examples as compared to many chemical precipitates. Precipitated chalk far outshines the natural varieties, and fine qualities of magnesia carbonate surpass this. Microscopic examination indicates that this latter consists of particles, clear and colourless, but very minute. White lead consists of particles equally minute and also transparent, but of a yellow brown colour by transmitted light; consequently, when seen in bulk it appears of a less pure white. But magnesia cannot be used as a pigment because it possesses no *body*, and the difference between the white lead and the magnesia in this respect depends upon the different refractive powers of the individual particles which compose the separate powders. They are both transparent in their individual particles, but the magnesia is more so. They are both bodies possessed of considerable refractive power, but the lead is more so. When air intervenes between their particles the reflective power of both so much exceeds that of air that they are highly reflecting and very slightly transmitting; but the less absorbing power of the magnesia makes it the whitest—the more reflecting of the two. But when oil intervenes, as would be the case if they were used for pigments, the refractive power of the magnesia so nearly coincides with that of the oil that much transmission and little reflection is the result, and this constitutes what painters call want of *body*. But the lead so greatly exceeds the oil in refracting power that its reflective property is not much interfered with, and even with its greater absorbing power it reflects much and transmits little light; and this is what painters call great *body*.

Another question which must often occur to our readers, and which has been ingeniously discussed by Mr. Proctor, is, whether anything is opaque. This can only be answered inductively from the results of numerous observations. Glass is only approximately transparent, for, if looked through edgewise, we find it stops a great deal of light. It is not so transparent as pure water, and even this, as has been shown by Tyndall, has a blue-green colour when light is passed through fifteen feet of it. Even air is far from transmitting all the light which enters it. A comet is almost incalculably more transparent than the earth's atmosphere. The light of a star passing through hundreds of thousands of miles of a comet's atmosphere and nucleus, loses less light than in passing through the thin stratum of air which covers the earth; yet even the comet is imperfectly transparent, and we do not know whether even the luminiferous ether itself allows the passage of light without some loss, but we know that glass is as much opaque compared with it as gold is when compared with glass; and from this we readily learn to believe that transparency and opacity are only comparative terms—that nothing transmits all the light, and nothing is entirely impervious to light; and this supposition is confirmed by experience. Even metals, which are usually taken as types of opacity, transmit light in thin films; and each metal has a proper colour of its own: thus, gold leaf viewed by transmitted light looks green, brown, violet, red, purple, or blue, according to the thickness of the film; silver leaf is grey-violet, purple, or brown; copper is green, antimony is grey, arsenic is brown, platinum grey, palladium grey, rhodium blue or brown, and charcoal grey. These illustrations show that most bodies transmit a coloured light, the colour deepening as the thickness increases, until it is so dark that we call it opaque. Not long ago light was believed to be reflected from the *surfaces* of bodies. And *now* it is only when we are on our guard that we bear in mind the thickness of matter required to reflect a ray. We know that in a soap-bubble we often see patches so thin that they do not reflect light, though they are still possessed of two surfaces. Faraday observed that some of the gold films he experimented with when reduced very thin by chemical means, lost part of their reflecting power, though they continued to be free from any material injury to their surface or integrity,

proving that some depth of matter is concerned in ordinary reflection. Different kinds of reflecting surfaces have different appearances; this is probably due to the effect produced upon the light by its passage into and out of that thickness of matter which is concerned in ordinary reflection. Of homogeneous matter, opaque gives metallic lustre and transparent gives vitreous; as a general rule, if not universal, we find the more nearly a substance approaches the metals in opacity the more it resembles them in the nature of its lustre. Thus sulphides are in many cases very nearly opaque, and very like metals in the nature of their lustre.

Some strangely interesting conclusions can be deduced from a consideration of the length of the waves of light in different media. The length of an undulation of violet light is seventeen millionths of an inch; the red undulation is twenty-six millionths; undulations longer or shorter than these not being visible. Again, the length of the light wave varies in the medium. An undulation in air measuring four will measure only two and a half when it enters glass, and will again elongate to its former measure on its exit. When an undulation passes from air into water, or into the humours of the eye it likewise becomes shortened. If we say that luminous undulations, which in air measure twenty-two millionths of an inch look yellow when they enter the eye, (that being the wave length belonging to what we call yellow light) we must also remember that they measure one-third less in that organ in consequence of its refracting power. We then come to the singular conclusion that the blue sky is yellow, sunshine is red, and the rosy tints of evening are not luminous at all till they enter the eye. If the colour depends upon the length of the light wave, and the length of the wave depends upon the refracting power of the medium through which it is passing, every beam of light changes colour; red it may be on its passing through the region of the stars, yellow or green it may be when it enters our earth's atmosphere, blue or violet when it enters water, non-luminous as it passes through glass. But if light which we perceive as violet while it exists in the aqueous humour of the eye was red originally, what colour must that light be which we perceive is red? Its undulations in air must be too long to be luminous at all. This introduces us to the solemn thought that all this vast universe is dark! Light only exists in the eye. It is only a sensation, a perception of that which in nature exists as a force capable of producing a sensation.

TONING BATHS.

During the past four or five years a great variety of toning baths have been proposed. Every one has plumed himself upon his own particular method—sometimes a secret one, but always assuming that it is superior to those of his neighbours. This state of affairs has led to a host of toning baths, which depart more or less from the conditions demanded by photographers, especially by amateurs, who, working less, do not obtain uniform results.

A toning bath, to be really good, must be *simple in composition, easy to use, successful in its results, and as economical as possible.*

Moreover, for albumenized paper, it must leave the albumen film as white and pure as before toning, and give in the half tones a colouring which is a lighter tone of the full colour. A taste, which we may venture to call a false one, has for a long time prevailed; it is that of giving to all commercial photographs a blue-black hue. By this the resemblance which constitutes the privilege of photographers, is lost. Thus chestnut or red hair is transformed into black, and it is seldom that this transformation does not destroy the resemblance to the original.

To gratify this vicious taste, it has been necessary to employ very deep printing, and strong toning; the light tones then disappear, leaving pure whites in the figures. These photographers, led away by a vicious example, degrade

photography, and cause it to imitate printing ink of a lithograph or mezzo-tint, at least, with this difference, which is supreme—the suppression of the half tone represented by the stipple of the engraver or the grain of the stone.

The precedent supplied was by the bath of M. Legray, now of bad repute, and entirely rejected, shows us the inconvenience of prescribing a bath without explaining its use, and without determining the operations which precede the toning.

The bath in question was a good one at the time it appeared, and it is so still, when the following recommendations are observed:—

1. The paper must be thick and strongly chlorinated.
2. The nitrate bath must be 20 per cent., and the paper floated upon it from six to eight minutes.
3. The proof must be immersed in the toning bath without previous washing.

These three recommendations demand a few words of re-consideration.

Thick paper absorbs a very great quantity of nitrate, a concentrated silver bath leaves a layer of nitrate on the surface of the paper, and when the proof is put into a toning bath, the 3 parts of chloride of lime to 1,000 parts of liquid, go in part to the nitrate to form chloride of silver, and thus remove from this bath its devouring power.

It is also to be remarked that it must be employed only in small quantity, just sufficient to cover the proof. It is more than probable that the paper was dried at the fire.

Some years ago, papers were thicker, and more strongly chlorinated. Concentrated baths were all the rage, and negatives developed with pyrogallic acid were almost all veiled or at least very hard. The proofs were exposed for hours in the sun, and were really printed in the papers. But we have changed all that. Now-a-days we must have thin paper of the finest grain. The strength of the baths has diminished, for this great quantity of chloride was not necessary. Negatives are developed with sulphate of iron, and are more transparent. The great demand for *carte de visite* portraits has compelled photographers to reduce the time of printing.

From the preceding we perceive that to judge of a formula it is quite essential that we should be placed in the same conditions as the author of it.

It is the want of development in the description of the process which causes all the failures; the consequence is a very legitimate hesitation on the part of the operator to try new formulae.

The authors of formulae for toning baths too often forget to indicate the conditions in which the paper must be placed in order to obtain all the effects promised from the bath they prescribe.

The paste of the paper is necessarily acid at various stages of its fabrication; from the variable degree of acidity to the starting point proceeds the multitude of toning baths, which are all indistinctly good with the papers for which they have been prepared.

The preparers of papers making use of papers more or less alkaline, sometimes in the inverse sense of their degree of acidity, thus furnish to photographers papers of which the series of the degree of acidity or alkalinity differ entirely from the composition of their toning bath.

The photographer, in his turn, changes this state of things by employing acid, alkaline, or neutral silver baths. He concludes his operations by a toning bath of *fixed* proportions, and is astonished at not having a constant result.

It would be much more astonishing if such marked differences gave similar results.

If the manufacturer could give us a neutral paper, we should require the preparer to deliver it to us in a neutral state also. We should then place it ourselves in conditions proper to receive the action of our toning baths.

This starting point not being obtained, it would be very difficult to require of the preparer to make a chemical analysis to ascertain the state of the paper, either before or

after preparation. The present state of things being chronic, what should the photographer do?

The reply, we believe, ought to be made as follows.

Render your toning baths more or less alkaline by increasing or diminishing the alkaline substance according as you may judge suitable for the paper you possess.

To be able to determine the proportions, the operator must resign himself to the task of testing a supply of paper, and obtain from the manufacturer and preparer a ream of paper, the pulp of which is identical, and the preparation of which has brought it, from time, to its normal state.

A ream of paper may be supplied so that the first sheet will be in exactly the same conditions as the last. The preparer, in albumenizing it, cannot deliver it to us in analogous conditions. He can supply a series of sheets exactly the same; but the first series will differ so much the more from the last in proportion as he has waited longer to restore his bath to its original position.

With manufacturers, an operation is performed which is the primary cause of all our vexation with respect to the paper; this operation is the *trriage*. Five, ten, or fifteen women, according to the extent of the factory, are charged with removing the sheets of paper to the drying room to put them into piles and form reams. One of the women turns first to the right and then to the left, piling and forming a ream of entirely different elements. A similar operation at the preparers still further removes the homogeneity that first existed.

One cause of failure most often to be dreaded is the yellow tint of the paper in the whites of the proof. It proceeds from various causes, one of which is the solarization of the paper before it is nitrated.

M. Niepce's experiments have shown us the *storing up* of the luminous rays, their retention and activity still existing after the lapse of several months. It is this solarization, so formidable in summer, which is the cause of those uniform yellow tints which the paper acquires before being put into the pressure-frame. Another solarization, less common, is that produced by the rays returned by solarized proofs placed in heaps when none are fixed. The nitrate baths, under the influence of organic bodies, also acquire an activity capable of yellowing the papers, and without apparent cause, they come out of the bath yellow in proportion to the activity of the cause.

Albuminous papers, either old or of bad quality, also acquire the property of yellowing, without our being able to trace the cause exactly. Probably, it is the state of the albumen, or of the pulp of the paper employed in its preparation, which causes this inconvenience.

Washing too many proofs in too small a quantity of water, or too prolonged a washing, in a water impregnated with lime, will also cause a yellow tint.

An impure silver bath, or one too strong or too weak, influences the desired tint. A negative too transparent, causing a too rapid solarization, gives also a grey proof in toning.

An incomplete toning, marbled and not uniform, arising sometimes from too great a reduction in the strength of the silver bath, and from too short a time being allowed for the paper to remain in contact with the argentiferous solution. The same effects may be produced when a great many proofs, placed one upon another, are not wholly in contact with the toning bath: bubbles of air, imprisoned between the proofs, form spots less deep in tone than that of the remainder of the proof. This kind of failure may be avoided by placing each couple of proofs back to back, at the bottom of the bath.

Some persons consider that the toning is assisted by not removing the excess of nitrate from the proof before toning, finding that it is of a better tint, and more beautiful. This observation is imperfect, for if this proof had been compared with the others after leaving the hyposulphite, it would have been seen that this fine tint and rapid toning was not preserved, and that the proof was not equal to those which had been slightly washed before toning. Not to wash the proof

is good, perhaps, for a bath the formula of which includes a substance which combines with the nitrate of the proof to aid the toning. This was the case with M. Legray's bath, quoted above.

We perceive that the causes of failure to the toning baths, without taking into account the spurious chloride of gold with which commerce is infected, for, most frequently, the chloride of gold is such only in name: it is either a chloride charged with hydrochloric acid entirely annulling the effect of the alkaline substance, which, with the chloride, composes the bath; or it is a double chloride of gold and soda, or gold and hyposulphite of soda, &c.—*Bulletin Belge de la Photographie*.

(To be continued.)

A FEW WORDS IN FAVOUR OF AN OLD FRIEND. —THE MALT PROCESS.

BY F. T. FASSITT.*

I MAKE the following communication with some degree of diffidence, fearing lest many of your readers will think that I am taking the back track in thus attempting to re-vivify comparatively an old process. I allude to the malt preservative of Mr. MacNair, as described by him in the *Photographic Notes*, 1860; but it is sometimes useful to glance retrospectively over the ground we have traversed, and by comparing our present modes of working with those we have discarded, see if in reality we have bettered ourselves.

Always a friend of progress, I have tried all the preservatives as they came forth, from the sticky abominations of honey, down through the whole category of Madam's preserves and jelly, until I reached the Fothergill; here I broke down and discarded the dry, and resolved to stand by the wet through thick and thin. However, upon the introduction of the malt process I was induced to give it a trial, and the result was so satisfactory that for over a year I worked nothing else, and I must say that during that time I produced the best negative I ever made. Upon the introduction of tannin, I gave it a trial, and found the results good, but in no respect superior to the malt; however, as everyone went head over heels into it, I followed the example, and have worked it with varying success until this spring, when, in company of some of the best amateurs of our city, I took a photographic trip through the northern section of our state. The plates used on this occasion were prepared with the greatest care. Fortunately I took developing solutions with me, and after the first day's work, I tried to develop a plate to which I had given, as I thought, a long exposure, but succeeded in obtaining hardly a trace of the sky; of course I had to stand the bantering of my companions upon the extreme sensitiveness of my plates. The next day, however, we increased the time of exposure, and in the evening I tried to develop some of my friends' plates, with the same result. Siccus, who was one of the party, suggested that I had neglected to put any pyro in the developing solution. Trusting that this might be the case, or that the pyro was at fault, we went on making long exposures and trusting to our resources at home to bring out the latent image; but alas! upon our return we found we were all in the same condition, our plates so insensitive to the actinic influence that neither fuming, carbonate of ammonia, nor hot water were of any avail; and our trip, photographically considered, was a failure.

We now commenced to hear complaints from other tannin workers, and found they were labouring under the same complaint. I now set to work to discover the cause. I changed my collodion and tannin; doctored the bath until everything was in first rate order, and made a few trial plates, and to my horror the result was the same. In my despair I made a visit to the lumber room, disinterred a large black box, for which at one time I had a great affection,—for you

* *American Journal*.

must know, Mr. Editor, that I am an inventive genius, and this black box was nothing more or less than a field apparatus for the wet process, and a very good one it is. I was studying how I could alter it so as to adapt it to the requirements of my whole-sized plates (it was intended for them), for you must know I am an inhabitant of the city of brotherly love, whose happiness, according to Mr. Thompson, consists in having a 6-inch globe lens and a Peace changing box, also that I am domiciled in the house with the quaker door-pull that will not work on Sunday (*vide* Thompson's visit to the city of brotherly love); and I will here state that I intend to discard the refractory bell, and substitute a first rate brass knocker, obtained from the grand emporium of that article, Wall Street, N. Y. Returning to the subject, it here struck me to try and see if by changing the preservative I could make my chemicals work. I prepared that night three malt and three tannin plates, using the same materials; on developing them after the same exposure, much to my surprise, the malt were all good, and tannin all bad. Since that I have made and exposed about twenty malt plates, made with the same chemicals, and they have all turned out good. I am at a loss to what cause to attribute our failure, as each one worked with his own materials, in his own way, and in his own laboratory; the only feature in common was that the plates were all bad.

For the benefit of those of your readers who have not tried the process, I will state briefly some of its advantages over the tannin, and the mode of working: first, from requiring less washing, the plates are more quickly prepared; second, the film adheres much better to the glass, and does not contract or form blisters, as the tannin is sometimes apt to do, particularly on large plates; it also stands the different methods of intensifying much better. The exposure is about the same, if anything, in favour of the malt; but one of its chief advantages is the use of an iron developer, and I find by using what Mr. Blanchard terms his iron intensifier, or the modification of it, as described in your journal of June 15th, that sufficient intensity can be obtained with iron alone, without the subsequent use of pyro or gallic acid and silver. Those of your readers who reside in this city, can save themselves the trouble of preparing the malt solution, by obtaining from the brewery what is termed "sweet wort;" I have used it for a long time, and find it as good as any I can prepare.

To make the malt infusion, take seven ounces of well bruised or ground malt, and digest it with twenty-four ounces of hot water, so that the mixture upon being well stirred will be at a temperature of 155° to 160°; do not let the temperature vary much from that for ten or fifteen minutes; then place the mixture before the fire and let it cool down to 130°, it should have acquired a sweet but not luscious taste, leave it to cool slowly, strain out the malt, and filter. By placing a small lump of camphor in the bottle, and keeping it in a coal vault, or cellar, it will remain fit for use a month or more before using it. Any good collodion will answer; bath same as you use for wet; coat and sensitize plate in the usual manner; on taking it from the bath, lay in a tray containing water, and rock it slightly; then either change the water or lay it in another tray whilst you coat and dip a fresh plate, then take the first plate out, drain for a moment, and pour on the malt solution so that it drives the water before it off the plate; pour on a fresh supply, flow it round a few times, pour off and set the plate up to dry. The last flowing of one plate will answer for the first of another.

To develop, lay the plate for a few minutes in a tray of water to soften the film, and then rinse well under the tap; lay the plate for about one minute in a tray containing enough twenty-grain bath solution to cover the plate; take out and drain as for wet collodion, then apply the iron developer:—

Sulphate of iron	12 to 15 grains
Acetic acid, No. 8	1 drachm
Water	1 ounce.

If sufficient intensity is not obtained, apply a two-grain pyro solution, or saturated solution of gallic acid, to which a few drops of twenty-grain silver solution has been added; the most beautiful result is produced with the latter, by laying the plate, supported at the corners, face downwards in the solution.

I have lately tried the iron intensifier, as given in your journal:—

Nitrate of silver	15 grains
Citric acid... ..	15 "
Water	1 ounce.

A few drops of this added to the iron developer gave all the intensity requisite, with great beauty of detail. The plates develop with great rapidity, and make very brilliant negatives; with regard to their keeping qualities, I have plates now on hand prepared in the above manner eighteen months ago, and they seem to work as well as those freshly made.

For positives on glass the malt is much superior to the tannin, giving a clear picture, the clear portions of the glass being perfectly transparent. I have seen some microscopic enlargements, made to exhibit in the lantern with the calcium light. They were fully equal to any made on albumen. The maker informed me he had tried tannin for the same purpose, but could not get the same result.

I must crave your indulgence for trespassing so much on your valuable space, but if anyone, like myself, shall be helped out of the mire, I shall esteem myself amply repaid. There are other uses of malt which will naturally suggest themselves to the mind of the photographer after a hard day's work, which I need not enlarge upon here, only cautioning them against the too free application of it, as it is liable to fog their impressions.

THE ÆSTHETICS OF PORTRAITURE.*

BY M. DISDERI.

We should omit one of the principal means of rendering a portrait resembling and beautiful, by not speaking of the choice and distribution of the light. It is a well-established fact that certain effects are favourable to some features and unfavourable to others. A clear and bright light will increase the features that are already too prominent, and give a hardness to the expression that does not really exist in the model. Again, if features that are naturally of too indistinct a character, be bathed in a soft, diffused light, they will become extremely undecided. The type is thus nearly effaced, and the resemblance and personality of the model entirely lost. If the light is allowed to fall from above, it will augment the projection of the forehead, throwing an energetic shadow over the eyes. The bridge of the nose, the lower lip, and the chin separate themselves, as it were, in clear lights, from the rest of the face. Such an effect would certainly be very inappropriate for the portrait of a young girl, whose forehead is smooth, profile calm, and of whom the soft blue eyes are the principal charm. Again, it would be too strong for a martial figure, as the thick moustache would throw a shadow over the whole of the lower part of the face, thereby giving a too violent an aspect to the whole.

However, if the artist has understood what we have said with regard to the composition of the portrait, and is willing to conform his lights and shades to the style that he has chosen, he will attain the greatest perfection in beauty and expression. By changing the direction of the light, he will soon perceive that all the different effects produced have different significations. Some are calm, sad, terrible; others graceful, gay, and joyful: each has its particular expression, independently, as it were, of either the nature or arrangement of the subject. It is, therefore, very evident that the general effects of the lights and shades should be appropriate to the character which has been chosen as the most favour-

* Continued from p. 245.

able to the portrait. If the portrait be that of a child, the scene should be conceived in a clear and smiling light, free from heavy and profound shadows. If, however, the portrait be that of a man of firm character, it would be necessary to proceed in quite a different manner, the sombre and ampler masses would be alternated by luminous ones—the shadows powerful, and the lights large and frank.

We will not, however, multiply these examples, as we have said enough to put intelligent and sincere artists in the right path. As to those who are not endowed with the fine sense of art and beauty, and whose only interest in photography is in a lucrative point of view, the enlightened public will sooner or later do them justice.

The reader will readily understand, after what we have just said with regard to the choice and distribution of light, of what great importance the position of the atelier is in photography. By preference, it ought to be constructed on the top of a house, so that no shadow or reflection from any neighbouring object may interfere with the effect chosen by the artist. It should have all the sides and roof of glass, so as to allow the light to penetrate equally from all four quarters and from above. It should also be provided with a system of curtains, some thicker than others, moved independently of each other by means of light pulleys, so as to enable the artist to direct the light at will, and diminish its light and intensity. The roof should form a sharp angle, and the glass should, like the curtains, be of a blue shade, so as to prevent the light being disagreeable to the eyes of the model.

The atelier should also be spacious, and unnumbered by instruments of different kinds, as is very often the case. All the photographic accessories, such as scenes, frames, and the like, should be placed in a neighbouring room, which is kept expressly for that purpose. A few objects of art and one or more comfortable chairs, are all that are required to furnish an atelier.

We will add a few words with regard to the choice of dress in the portrait. We hope that the explanations which we have already given have sufficed to show that the dress should be in keeping with the age, character, and habits of the model, and that the photographer should not always content himself with any costume that may be presented to him, as exaggerated dress is almost sure to spoil the portrait. Here is one case, however, in which no choice is allowed to the photographer, namely, when the person wears a military uniform, or an official dress; here, the exact reproduction of the costume is an essential condition to the resemblance. The operator will, of course, know, from his own taste, how to distribute and arrange the dress of his model, so as to obtain optical unity and beauty. We will here call the attention of the operator to a point on which we have as yet but slightly touched, namely, that all the combinations that we have just enumerated as requisite conditions for obtaining a good portrait, may be rendered of no effect by a false choice of colour in the dress of the model. The colours which are the most luminous to the eye, do not always produce the most energetic effects. For instance—red, orange, and yellow, are almost without action; green acts but feebly; blue and violet are reproduced very promptly. Thus, a person of very fair complexion must not be dressed in either green, orange, or red, as the lights would be too prominent, and the whole portrait would lack energy and detail. The artist is thus obliged to be very particular as to the choice of dress in his model.

Portrait colouring does not belong to the art of photography, and we will, therefore, touch upon it but very slightly. This sort of work should only be confided to special and extremely talented artists. It is not only necessary to avoid losing the resemblance, but the colours used must not be so opaque as to cover and render invisible the shades that have been produced by the light. A photographer who is not a stranger to the laws of colour, may greatly facilitate the task of the painter by a favourable disposition of the lights, tones, &c.

It results, from what we have just read, that it must be difficult to obtain a good portrait in which there is both resemblance and beauty; and that the art of photography can only be acquired by long and constant observation of nature, and patient study. It may be thought that so many difficulties would scarcely meet the exigencies of a production which is required to be rapid and not costly. We would answer, that it is not commerce, but art, that is here implied; and that art seeks after beauty, at whatever price it may be realised. The enlightened part of the public fully appreciates this difference. Why should people address themselves exclusively to photographers who ask the highest prices for their pictures, if not for this reason? The materials and chemical substances are precisely the same in a bad portrait as a good one. The real cause is the same as that which creates the inestimable value of those small pieces of canvas signed "Decamps" and "Delaeroix."

PREPARATION OF SULPHOCYANIDE OF AMMONIUM.

BY E. MILLON.*

Mix 150 ounces of commercial liquor ammonia with 20 ounces of bisulphide of carbon and 150 ounces of alcohol (86 per cent.), and allow it to stand 24 hours. The mixture assumes an orange-yellow colour. After the expiration of the time mentioned, the fluid is well stirred, and then about two-thirds are distilled off. The distillate contains nearly all the alcohol holding in solution much sulphocyanide of ammonium; this alcohol may be used two or three times with fresh quantities of ammonia and sulphide of carbon. The residual third in the retort contains the sulphocyanide of ammonium.

As soon as the alcohol is almost wholly distilled over, the fluid, which before was quite clear, becomes muddy, and at the same time loses its colour. It is then carefully evaporated on an open fire to crystallization. The crystals contain flakes of sulphur, which is removed by solution and filtration. By a second evaporation the salt is obtained in very long crystals and in a very pure condition.

DOINGS OF THE SUNBEAM.†

HERE is a square of crown glass three-fourths as large as a page of the *Atlantic Monthly*, if you happen to know that periodical. Let us brush it carefully, that its surface may be free from dust. Now we take hold of it by the upper left-hand corner and pour some of this thin syrup-like fluid upon it, inclining the plate gently from side to side, so that it may spread evenly over the surface, and let the superfluous fluid drain back from the right-hand upper corner into the bottle. We keep the plate rocking from side to side, so as to prevent the fluid running in lines, as it has a tendency to do. The neglect of this precaution is evident in some otherwise excellent photographs; we notice it, for instance, in Frith's Abon Simbel, No. 1, the magnificent rock-temple façade. In less than a minute the syrupy fluid has dried, and appears like a film of transparent varnish on the glass plate. We now place it on a flat double hook of gutta-percha, and lower it gently into the nitrate of silver bath. As it must remain there three or four minutes, we will pass away the time in explaining what has been already done.

The syrupy fluid was *iodized collodion*. This is made by dissolving gun-cotton in ether with alcohol, and adding some iodide of ammonium. When a thin layer of this fluid is poured on the glass plate, the ether and alcohol evaporate very speedily, and leave a closely adherent film of organic matter, derived from the cotton, and containing the iodide of ammonium. We have plunged this into the bath, which contains chiefly nitrate of silver, but also some iodide of silver,—knowing that a decomposition will take place, in consequence of which the iodide of ammonium will become changed to the iodide of silver, which will now fill the pores of the col-

* *Journal de Pharmacie et de Chimie.*

† Continued from page 346.

collodion film. The iodide of silver is eminently sensitive to light. The use of the collodion is to furnish a delicate, homogeneous, adhesive, colourless layer, in which the iodide may be deposited. Its organic nature may favour the action of light upon the iodide of silver.

While we have been talking and waiting, the process just described has been going on, and we are now ready to take the glass plate out of the nitrate of silver bath. It is wholly changed in aspect. The film has become in appearance like a boiled white of egg, so that the glass produces rather the effect of porcelain, as we look at it. Open no door now! Let in no glimpse of day, or the charm is broken in an instant! No Sultana was ever veiled from the light of heaven as this milky tablet we hold must be. But we must carry it to the camera which stands waiting for it in the blaze of high noon. To do this we first carefully place it in this narrow case, called a *shield*, where it lies safe in utter darkness. We now carry it to the camera, and having removed the ground glass on which the camera-picture had been brought to an exact focus, we drop the shield containing the sensitive plate into the groove the glass occupied. Then we pull out a slide, as the blanket is taken from a horse before he starts. There is nothing now but to remove the brass cap from the lens. That is giving the word Go! It is a tremulous moment for the beginner.

As we lift the brass cap, we begin to count seconds,—by a watch, if we are naturally unrhythmic,—by the pulsations in our souls, if we have an intellectual pendulum and escapement. Most persons can keep tolerably even time with a second-hand while it is traversing its circle. The light is pretty good at this time, and we count only as far as thirty, when we cover the lens again with the cap. Then we replace the slide in the shield, draw this out of the camera, and carry it back into the shadowy realm, where Cocytus flows in black nitrate of silver, and Acheron stagnates in the pool of hyposulphite, and invisible ghosts, trooping down from the world of day, cross a Styx of dissolved sulphate of iron, and appear before the Rhadamanthus of that lurid Hades.

Such a ghost we hold imprisoned in the shield we have just brought from the camera. We open it and find our milky-surfaced glass plate looking exactly as it did when we placed it in the shield. No eye, no microscope, can detect a trace of change in the white film that is spread over it. And yet there is a potential image in it,—a latent soul, which will presently appear before its judge. This is the Stygian stream,—this solution of proto-sulphate of iron, with which we will presently flood the white surface.

We pour on the solution. There is no change at first; the fluid flows over the whole surface as harmless and as useless as if it were water. What if there were no picture there? Stop! what is that change of colour beginning at this edge, and spreading as a blush spreads over a girl's cheek? It is a border, like that round the picture, and then dawns the outline of a head, and now the eyes come out from the blank as stars from the empty sky, and the lineaments define themselves, plainly enough, yet in a strange aspect—for where there was light in the picture we have shadow, and where there was shadow we have light. But while we look it seems to fade again, as if it would disappear. Have no fear of that; it is only deepening its shadows. Now we place it under the running water which we have always at hand. We hold it up before the dull-red gas-light, and then we see that every line of the original and the artist's name are reproduced as sharply as if the fairies had engraved them for us. The picture is perfect of its kind, only it seems to want a little more force. That we can easily get by the simple process called "intensifying," or "redeveloping." We mix a solution of nitrate of silver and of pyrogalllic acid in about equal quantities, and pour it upon the pictured film and back again into the vessel, repeating this with the same portion of fluid several times. Presently the fluid goes brownish, and at the same time the whole picture gains the depth of shadow in its darker parts which we desire. Again we place it under the running water. When it is well washed, we plunge it into this bath of hyposulphite of soda, which removes all the iodide of silver, leaving only the dark metal impregnating the film. After it has remained there a few minutes, we take it out and wash it again as before under the running stream of water. Then we dry it, and when it is dry, pour varnish over it, dry that, and it is done. This is a *negative*,—not a true picture, but a reversed picture, which puts darkness for light, and light for darkness. From this we can take true pictures, or *positives*.

Let us now proceed to take one of these pictures. In a small room, lighted by a few rays which filter through a yellow curtain, a youth has been employed all the morning in developing the sensitive conscience of certain sheets of paper, which came to him from the manufacturer already glazed by having been floated upon the white of eggs, and carefully dried, as previously described. This "albumenized" paper the youth lays gently and skilfully upon the surface of a solution of nitrate of silver. When it has floated there a few minutes, he lifts it, lets it drain, and hangs it by one corner to dry. This "sensitized" paper is served fresh every morning, as it loses its delicacy by keeping.

We take a piece of this paper, of the proper size, and lay it on the varnished, or pictured side, of the negative, which is itself laid in a wooden frame, like a picture-frame. Then we place a thick piece of cloth on the paper. Then we lay a hinged wooden back on the cloth, and by means of two brass springs, press all close together.—the wooden back against the cloth, the cloth against the paper, the paper against the negative. We turn the frame over and see that the plain side of the glass negative is clean. And now we step out upon the roof of the house into the bright sunshine, and lay the frame, with the glass uppermost, in the full blaze of light. For a very little while we can see the paper darkening through the negative, but presently it clouds so much that its further changes cannot be recognized. When we think it has darkened nearly enough, we turn it over, open a part of the hinged back, turn down first a portion of the thick cloth, and then enough of the paper to see something of the forming picture. If not printed dark enough as yet, we turn back to their places successively the picture, the cloth, the opened part of the frame, and lay it again in the sun. It is just like cooking; the sun is the fire, and the picture is the cake; when it is browned exactly to the right point, we take it off the fire. A photograph printer will have fifty or more pictures printing at once, and he keeps going up and down the line, opening the frames to look and see how they are getting on. As fast as they are done, he turns them over, back to the sun, and the cooking process stops at once.

The pictures which have just been printed in the sunshine are of a peculiar purple tint, and still sensitive to the light, which will first "flatten them out," and finally darken the whole paper, if they are exposed to it before the series of processes which "fixes" and "tones" them. They are kept shady, therefore, until a batch is ready to go down to the toning room.

When they reach that part of the establishment, the first thing that is done with them is to throw them face down upon the surface of a salt bath. Their purple changes at once to a dull red. They are then washed in clean water for a few minutes, and after that laid, face up, in a solution of chloride of gold, with a salt of soda. Here they must lie for some minutes at least; for the change, which we can watch by the scanty daylight admitted, goes on slowly. Gradually they turn to a darker shade; the reddish tint becomes lilac, purple, brown, of somewhat different tints in different cases. When the process seems to have gone far enough, the picture is thrown into a bath containing hyposulphite of soda, which dissolves the superfluous, unstable compounds, and rapidly clears up the lighter portions of the picture. On being removed from this, it is thoroughly washed, dried, and mounted, by pasting it with starch, or dextrine, to a card of the proper size.

The reader who has followed the details of the process may like to know what are the common difficulties the beginner meets with.

The first is in coating the glass with collodion. It takes some practice to learn to do this neatly and uniformly.

The second is in timing the immersion in the nitrate of silver bath. This is easily overcome; the glass may be examined by the feeble lamp-light, at the end of two or three minutes, and if the surface looks streaky, replunged in the bath for a minute or two more, or until the surface looks smooth.

The third is in getting an exact focus in the camera, which wants good eyes, or strong glasses for poor ones.

The fourth is in timing the exposure. This is the most delicate of all the processes. Experience alone can teach the time required with different objects in different lights. Here are four card-portraits from a negative taken from one of Barry's crayon pictures, illustrating an experiment which will prove very useful to the beginner. The negative of No. 1 was exposed only two seconds. The young lady's face is very dusky on a very dusky ground. The lights have hardly come

out at all. No. 2 was exposed five seconds. Undertimed, but much cleared up. No. 3 was exposed fifteen seconds, about the proper time. It is the best of the series, but the negative ought to have been intensified. It looks as if Miss E. V. had washed her face since the five-seconds picture was taken. No. 4 was exposed sixty seconds, that is to say, three or four times too long. It has a curious resemblance to No. 1, but is less dusky. The contrasts of light and shade which gave life to No. 3, have disappeared, and the face looks as if a second application of soap would improve it. A few trials of this kind will teach the eye to recognize the appearances of under and over exposure, so that, if the first negative proves to have been too long or too short a time in the camera, the proper period of exposure for the next may be pretty easily determined.

The printing from the negative is less difficult, because we can examine the picture as often as we choose; but it may be well to undertime and overtime some pictures, for the sake of a lesson like that taught by the series of pictures from the four negatives.

The only other point likely to prove difficult is the toning in the gold bath. As the picture can be watched, however, a very little practice will enable us to recognize the shade which indicates that this part of the process is finished.

(To be continued.)

Proceedings of Societies.

AMATEUR PHOTOGRAPHIC ASSOCIATION.

A COUNCIL meeting of the Amateur Photographic Association was held, July 6, at 12, York Place, Portman Square, the Right Honourable the EARL of CAITHNESS, Vice President in the chair. The minutes of the last meeting having been read and confirmed, the following members and subscribers were proposed and elected:—

Lady Foley; Lt.-Col. Biggs; Mrs. Brownlow; John Taylor, Esq.; J. C. Arkwright; John Lloyd, Esq.; Miss L. E. Ramsden; R. W. Morris, Esq.; Mrs. M. S. Harrison; — Gale, Esq.; W. Saville, Esq.; John Douglas, Esq.; The Honourable W. Carrington; T. Brownrigg, Esq.; W. R. Cherrill, Esq.; R. L. McMorland, Esq.; Dr. T. M. Lowndes; E. Coward, Esq.; Mrs. C. Browne; T. Herney, Esq.; Captain Poulton; A. Armour, Esq.; George Barr, Esq.; Robert Verschoyle, Esq.

The Secretary laid before the meeting the statement which he had been directed to prepare, relative to the subscriptions, by which it appeared they were greatly in arrear. The secretary was therefore instructed to send a circular to the members and subscribers, to impress upon them the importance of paying their subscriptions when due; viz., the 1st June each year; and after some discussion it was proposed by his Grace the Archbishop of York, seconded by the Viscount Ranelagh, and decided by the meeting, that henceforth no person elected shall be considered a member of the association until the first subscription be paid, which must be within three months of notification of such election; and that any member whose subscription remains unpaid for one month, after a second notice from the secretary, shall be considered as having withdrawn from the society.

The secretary then laid before the meeting between two and three thousand pictures, being the contributions of members of the present year, comprising every variety of subjects and views in almost every part of the globe.

Mr. Glaisher then read a statement of the numbers, sizes, and relative excellence of this year's pictures, as determined in conjunction with Mr. Shadbolt, of which the following is a condensed abstract:—Pictures of the highest class (Class 1) thirty, contributed by the following members:—By Major F. Gresley, 6; by W. D. Chidson, 4; by W. Chureh, jun., 3; by A. Henderson, 3; by Lt.-Col. Biggs, 2; by T. W. Rimington, 2; and one each by the Honourable W. W. Vernon; Lt.-Col. the Honourable D. F. do Ross; J. A. Rolls; H. St. V. Ames; Lt. E. C. Impey; Major Innes; F. Beasley; Baynham Jones; Miss E. Scott; and E. R. Hall.

Class 2 comprises 82 pictures, contributed by 38 members, amongst whom Lt. Impey stands first, having no less than 16; A. Henderson, 8; Thomas Pryce, 4; F. E. Currey, 3; the Honourable W. W. Vernon, 3; Dr. Hallifax, 3; and Col. Biggs, 3.

Class 3 comprises one hundred and seventy-six pictures, contributed by sixty-two members. Here again Lt. Impey stands

first, having 22; T. W. Rimington, 18; A. Henderson, 12; Col. Biggs, 9; Captain Hutton, 7; T. Pryce, 6; W. C. Moens, 5; J. Bevington, 5; and the Honourable and Reverend A. Campbell, 2.

Class 4 comprises two hundred and twenty pictures, amongst which are many which are excellent, by most of the members already mentioned, and W. D. Hemphill, M.D., Mrs. C. S. Harris, J. A. C. Brauffill, H. Clayton, T. Ebbage, Captain Playfair, W. Hartford, Vero Taylor, Lieutenant-Colonel Holden, O. J. Jones, H. B. Bowman, G. S. Penny, J. H. Ravenshaw, R. Murray, F. J. Oliver, D. W. Hill, T. Martin, Lt. Noverre, T. Smith, T. Fenn, J. A. Melany, Major Burt, Sir M. Cave, Bart.; Rev. F. Gutierrez, D. Hornby, R. le Gricce, C. Crosthwaite, A. Suzanne, Major Houghton, Lady Matheson, Captain Davies, the Viscountess Jocelyn, F. R. Barclay, J. C. Arkwright, Major Russell, and some very interesting photographs of the moon by P. J. Kaiser, of Leyden Observatory. There is also a life-like portrait of the Prince of Wales, by the Earl of Caithness.

Class 5 comprises the remainder of the pictures, mostly good, many very good, and worthy of special notice, did space permit.

The following prizes were awarded:—

1st Prizes.—Baynham Jones, Esq., for a 10 × 8 picture, "A Misty Morning;" and Major Gresley for a pair of 10 × 8 pictures, "Sunshine" and "Shade."

2nd prize.—To W. D. Chidson, Esq., for a pair of 8 × 6 pictures, "Going a Milking," and "Been a Milking."

3rd prize.—To A. Henderson, Esq., for a 9 × 7 picture, "The Mountain Maid," (Canadian steamboat; instantaneous.)

4th prizes.—To Lt. E. C. Impey, for a 12 × 10 picture, "Hill and Tank," at Ulwur, Hindostan, and T. W. Kimington, for a 10 × 8 picture, "The Hall of Columns, Karnac." Total value, 27 guineas.

The council also decided that a "certificate of honourable mention" should be given to the following members: Lt. E. C. Impey, The Honourable W. W. Vernon, A. Henderson, W. Church, Jr., T. W. Rimington, J. A. Rolls, Lt. Col. Biggs, H. St. V. Ames, Major Innes, F. Beasley, E. R. Hall, Miss E. Scott, T. Pryce, F. E. Currey, Dr. Hallifax, Capt. Hutton, W. C. Moens, J. Bevington, The Honourable and Reverend A. Campbell, Major Burt, D. Hornby, R. le Gricce, P. J. Kaiser, H. Clayton, Vero Taylor, and Mrs. C. S. Harris. No prize was awarded for stereographs, as although the average quality of this class of pictures is above that of last year, yet no particular picture was considered of sufficient excellence to merit a prize. The Rev. H. B. Ingram was elected member of council, in place of John Peun, Esq.

The Secretary put the question to the meeting, whether the proposed Exhibition should be held now or not, and after some discussion it was decided that as the season is so far advanced it shall be held at the close of the year, provided the necessary funds can be raised.

A vote of thanks was passed to the Referees for the time and attention they had devoted to the affairs of the Association.

A vote of thanks was also passed to A. Glendenning, Esq.

Dr. W. D. Hemphill, and S. H. Maugham, Esq., for their great and disinterested exertions in behalf of the Association, and for the large number of members and subscribers who had joined the Society through their efforts.

The proceedings then terminated.

A. J. MELHUIS, Hon. Sec.

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, July 22nd, 1863.

M. BLANQUART EVRARD has addressed a *Mémoire* to the Imperial Society of Lille, "On the Intervention of Art in the Formation of Photographic Negatives." In a letter to the Paris Photographic Society, accompanying this Memoir, he states: "The photographic proof being inevitably the unvarying copy of the model placed opposite the objective, the artist can modify the effect and value of the picture, so that the work which leaves his hand will be his own, and as

in the other products of art, bear the stamp of his individuality."

There is, therefore, unless I deceive myself, a new road open to photography: I should add, that apart from this point of artistic view, which is the most important part of my study, there is another purely photographic, to which I ask permission to call the attention of the Society.

We know that photography is condemned to produce in one and the same *unit of time*, a combination of objects possessing extremely diverse photogenic properties. Hence arise the disparities of hue and the false effects we frequently encounter, even in the most magnificent proofs; and if in certain pictures the waves of the sea resemble black ink, and the guides upon Mont Blanc resemble chimney-sweeps, it is because it is impossible for the most skilful operators to make the objects appear with their local tones in the same space of time as luminous clouds, glaciers, or snow. This example among a thousand will suffice to make us appreciate the advantage which may be derived from the possibility of completing, by a subsequent exposure, those parts of the image where the action of the light has been insufficient during the exposure in the camera, or by the attenuation, by purely chemical means, of the lights too vividly marked during the first exposure upon the parts too strongly lighted.

Upon this communication the president, M. Regnault, remarked, that the assistance M. Blanquart Evrard's researches could render to photographers consisted in the power it gave them of modifying at will the effects of a given negative. To turn it to useful account, it would be desirable to make two negatives, so that one might be submitted unhesitatingly to every kind of experiment, and that if damaged, there would remain the other to fall back upon.

M. Poitevin, who presented the Society with some proofs obtained upon enamel by vitrification, expresses himself on this subject in the following terms:—

"I do not for a moment wish to enter upon any discussion on the various processes which have been and are now employed by other photographers to produce photographic impressions by means of vitrifiable culvers upon glass, porcelain, or enamel; although very probably the insolubilizing of light upon bichromatized organic matter is the basis of these various methods, bitumen of Judca having, I believe, been abandoned for some time past by the skilful operator, who extolled its use in 1854. You know, also, that previous to 1855 no one had employed the bichromates with organic matters to produce permanent pictures on paper or other surfaces, before the announcement I made at this period.

"The vitrified proofs upon enamel which I submit to the appreciation of the Society, have been obtained by my process on glass, prepared with per-chloride of iron and tartaric acid, which, since 1860, I employed in carbon printing. In the present instance I employ instead of carbon an enamel in impalpable powder to develop the picture. I transfer this latter, by means of a film of collodion, on to a plate of enamelled copper, or porcelain, &c., and I fix it by means of a sufficient heat, in an enameller's muffle."

M. Beyrich, of Berlin, presented to the Society some vases of glass porcelain, &c., of various forms, to which he has found the means of applying ordinary photographic proofs.

His process is based upon the discovery he has made of a paper from which the sensitive coating is easily detached; this paper, treated in the ordinary manner, resists until after it has passed through the toning baths; it is then only that it becomes easy to separate the printed picture from it as a sort of film which may be glued upon glass or porcelain vessels, whatever be their form. This application made to small ground glasses constitutes images visible by transparency analogous to lithophanes. Hitherto, M. Beyrich has only succeeded in transporting the picture in this manner to vases as a decoration, but he, at the same time, seeks the means of baking these pictures, so as to convert them into vitrified proofs. Success has not yet crowned his efforts; the gold deposited upon the silver during the toning, yields in

the muffle only a dead, light rose colour, but by modifying this first attempt M. Beyrich hopes soon to succeed in converting this proof into vitrified pictures.

WHAT A LENS WILL COVER—ANGLE OF VIEW —EQUIVALENT FOCUS.

SIR,—Being in search of a good landscape lens to use in a camera for 11 by 9 pictures, for general purposes, and also for engineering subjects, bridges, &c., where a large angle of view is required, say 60° or 65° , I ask the favour of your advice as to the *form* of lens best adapted for such purpose. It is not a question of maker, as I am satisfied there is little to choose between three or four of our best manufacturers; but, as to what a lens will cover, I am thoroughly convinced (apart from the evidence published in a contemporary, respecting a picture of Whippingham Church, by Mr. Ernest Edwards), that the triplet form does cover a very wide field. I made the experiment a few days since of taking a view 11 by 9, with the No. 1 triplet of 7 inches back focus, and another the same size from the same point, with a caloscopic of $11\frac{1}{2}$ in. back focus. The triple gave a larger circle of light, and better defined to the edges than the caloscopic; the latter seemed to soften down the outer edge of the circle, like a vignette, a much greater distance into the field, while the triple worked much closer to the outer line, and then finished off more abruptly, or with a sharper edge. Of course, the image formed with the $11\frac{1}{2}$ in. focus lens, was larger than the other, and, consequently, the angle of view, smaller.

I next turned my attention to some pictures sent me by a friend who swears by the "aplanatic" form, they were very good but accompanied with a note "taken with the aplanatic lens, 9 in. focus, including an angle of nearly 70° ," although the base line of the picture only measured $8\frac{1}{2}$ inches. This is an error committed, I am afraid, too frequently, in stating the angle included by various lenses; it is a subject that I much wish some of your numerous contributors would take up, and treat in a popular manner with diagrams, &c., for, according to my calculation, the pictures in question would only include an angle of a trifle less than 50° . This is, perhaps, as much as most photographers care for, and certainly is a wonderful improvement on the old form, which only includes about 38° ; yet in stating the angle comprised in a given picture, and by a certain lens, it ought to be done correctly, or others are likely to be misled by it.

I am going on the supposition that in speaking of the angle of view it is measured on the horizontal or base line of the picture, and not diagonally. I find that to include an angle of 60° on a plate 11 by 9, I shall require a lens of about $9\frac{1}{16}$ in. focus. Now, in searching the lists of our best makers, I find no such focus quoted; there is a triplet of 10 in. back focus. I wish all could be induced to state the true focal length, we then should not be bothered with such remarks as *nominal* and *real* focus, which are very perplexing. Now if the back focus is 10 in., the real focus will probably be 1 in. or $1\frac{1}{2}$ in., more. This brings me to the next nearest advertised lens, the aplanatic of 12 in. focus. Now, either of these for a picture, 11 by 9, will not include in round numbers more than 50° ; there is, then, nothing left to fall back upon but the aplanatic of 9 in. focal length; this would give the required angle, but whether it would work satisfactorily in other respects I am wishful to know, and also if at the same time you could inform me the equivalent focus of the No. 2 triplet of 10 inches back focus. While writing the foregoing I have received the *Notes* for the 15th inst., in which Mr. Sutton speaks favourably of a triplet lens of 14.6 focus for 12 by 10 pictures; now this, according to my previous mode of calculation, only gives an angle of 45° . Should I be in error, doubtless you will put me right.

TANNO-GLYCERINE.

[We do not know of any lens at present catalogued which will give you an angle of 60° or 65° on 11 by 9 plates. The only form of lens which will give the required angle

satisfactorily is the triple, and the focus of No. 1 is too short, and that of No. 2 too long to give the angle required on 11 by 9 plates. The No. 2 triple has an equivalent focus of a fraction over 11 inches, and would give you on 11 by 9 plates an angle of 52° , or a trifle more. This is the nearest to your requirements of any existing lens which we know. If you especially require the results to which you refer, we have no doubt that Mr. Dallmeyer would make a special lens for you of the desired focus. The aplatic would not, as you have seen, give the angle, and the distortion for engineering subjects would be intolerable.

It is a very difficult thing to popularize the subject to which you refer. When the equivalent focus of the lens is known, it is very easy to any one familiar with mathematics to ascertain the angle included in a given picture. As we stated a few weeks ago, those who have access to a table of tangents may easily make the calculation by measuring the angle formed by the equivalent focus and the base line of the picture, the amount of subject included is twice the tangent of half that angle, as we have before stated. Perhaps the simplest popular method would be to proceed as follows: ascertain the equivalent focus of the lens, either from the optician, or by direct experiment, as we have described on a former occasion. Then measure the horizontal line of the picture; upon this line let fall a perpendicular the length of the equivalent focus. Now, with a protractor measure the resulting angle, which will give, with sufficient accuracy, the amount of subject included. Your calculations as to the angle included by the respective lenses referred to in your letter are correct. The origin of the method of stating the foci of lenses as measured from the back glass originated in the importance of giving some idea as to kind of camera required, and the space necessary between the lens and ground glass. It is a great pity, however, that the equivalent focus is not also stated. The practice is, however, becoming more general.—Ed.]

THE LIME TONING BATH AND ITS DIFFICULTIES.

DEAR SIR,—I am an unfortunate man; a skeleton hangs in my photographic cupboard, and his name—no bad nomenclature considering his chemical composition—is *lime*. I am an old practitioner and printer, and for years met with such success by the old process of printing that it was with difficulty I could bring myself to adopt the new. No doubt I am looked upon as an old-fashioned fellow with out-of-date ideas when I say that I am prepared to produce from any given good negative a better print in point of tone, depth, and *modelling* than can be got from it by any of the new processes. However, in deference to the spirit of the age, I adopted the new systems, and consoled myself for any deficiency I found with the idea that the prints might possibly be more permanent. I found no difficulty in getting as good effects as other people with the acetate, the carbonate, and the phosphate; in fact I went on conquering, and, as I thought, to conquer; but at last came my check—my Waterloo—and the destroying enemy is the oil-shop product I have named above. Seduced by the hope of getting those “rich blacks” with “warm flesh tints,” I began with Ommeganck, then I carefully tried those formulæ given in the News as the “Experiments at Ryde,” with your own modification. Last of all I have tried Parkinson’s, as given in your last number, but the result in all is the same. The difficulty begins at once, I may truly say, meets me in lime-ine, for no sooner are the prints immersed than free chlorine attacks them and the bleaching process begins. Whether I make the bath with hot or cold water, or add the lime when the solution is milk-warm, according to one of your correspondents, or try it within an hour or a week, (your own modification I tried each day successively for ten days), the result is always the same: of course you know the exact effect, and I need not describe it. Shakespeare in his prescience must have caught a glimpse of “printing difficulties,” for who could better describe a “mealy print”?

“And a most instant tetter, bak’d about
Most vile and lazar-like, with loathsome crust,
My wholesome body.”

I may mention, that in addition to every conceivable precaution, I have more than once “changed my oil-shop,” but all samples of the devouring fiend seem alike. What can I do? like the ancient waggoner stuck in the mud, I invoke the gods—the deities of the photographic press, and make my first appeal to you as the Jupiter Tone-ans of that august body. Will you simply state in your column of answers if I was wrong in anything, except the quality of the lime. In my working out Parkinson’s formula, I saturated a small bottle full of water, with chloride of lime, shaking it well for some minutes, this I filtered and saturated it with whiting, and filtered that compound. Of this I took the exact quantity (rather more than $1\frac{1}{2}$ drachms), and added 35 ounces of water with 2 grains of gold—after 24 hours, I tried it, and again in 48 hours, but in both cases the same and the old failure—bleaching and meanness.

Meal, meal, meal,
On every print immersed,
Meal, meal, meal,
The last as well as the first.
It’s O! for the process old
That gave me such beautiful tints,
The honest compound of hypo and gold,
That never spoiled my prints.
Meal, meal, meal,
By Ommeganck, Parkinson, Hughes.
Meal, meal, meal,
By every receipt in the News.
An anomaly strange will appear,
If things in this fashion keep,
I shall find that bread is exceedingly dear,
While meal is so very cheap.
Meal, meal, meal,
If I float ten minutes or more,
Meal, meal, meal,
If I only float for four.
Both kinds of Saxe and Rice,
Both kinds of Rice and Saxe,
Oh, grant, kind Heaven, a short reprieve
From its venomous, deadly attacks.

—I am, dear sir, yours truly,

CHA-MEAL-ION.

[We are quite familiar with the difficulties our correspondent describes so pathetically. They proceed from excess of free chlorine, which, having such an affinity for silver, and finding it in a finely subdivided state in the print, the most convenient forum for its action, at one attacks it, and turns it into white chloride of silver, producing the lazar-like tetter of meanness. The remedy is to lessen the proportion of chloride of lime, and with a given sample of paper, gold, and lime, arrive by experiment at the proper proportion. Each of these articles vary in exact quality, and hence the variety of result when a constant formula is adhered to. Success is certain if the right method be followed. We have succeeded by pursuing the method we have described, others have succeeded by the respective formulæ for which they stand sponsors. Experiment is troublesome, it may be said. Very good: then there are other methods, giving good, but not quite the same results, which are less troublesome. Our correspondent may try a lime bath with which we have seen no failure by obtaining a bottle of Sutton’s calcio-chloride of gold, and diluting it considerably more than is recommended in the directions for use. The old hypo and gold bath gave less trouble, but rarely such pure whites or rich tones as the alkaline bath, and never better than the best results of the latter, with all the greater risk of becoming yellow. If our correspondent will send us a directed envelope, we will forward him a lime-toned print, in which there is no meanness, but a rich black tone.—Ed].

Photographic Notes and Queries.

OLD IRON DEVELOPER v. NEW.

DEAR SIR,—I have with many of your readers been much troubled with fogged and dirty negatives during the last two or three weeks.

This has been the more annoying, as, putting faith in the

bright sunshine, I had made many appointments with friends who wished to be "taken," most of whom have been grievously disappointed; but this was not the case with all, for I accidentally discovered that a stale developer gave brilliant results, while a newly mixed one produced faint and stained negatives which were, moreover, most difficult to intensify.

On the first occasion when this came under my notice, I had by me about half an ounce of an old developing mixture of sulphate of iron and ammonia, from 10 to 30 grains to the ounce, but the strength was unknown, the mixture being, in fact, residues of old developers, and which I had before used with good results. In the midst then of my troubles, one morning, when baths, new and old, neutral and acid, and newly mixed developers of every kind (iron), gave nothing but these unsatisfactory negatives, I turned to my old developer, and at once the negative came out clear and red. This I tried two or three times and with the same satisfactory results, as long, in fact, as this precious mixture lasted; after that, all was dull and dirty. I racked my memory to recall the exact composition of this, but in vain. About four days afterwards, I again experienced this peculiarity in a developer, which had nothing that I knew to recommend it, except that it had been mixed four or five days, being, in fact, one that had failed on the previous occasions.

It then occurred to me, that its merit might be due to its age, and, acting on this notion, I have since used developers which have been mixed four or five days, with the best effect.

A sulphate of iron developer which had been made about ten days, I also found to give clear negatives, though showing signs of decomposition when poured on the plate.

The effect above stated was so strikingly suggestive of the advantage under some circumstances of stale developers that I have communicated it to you: and the fact also raises two questions—whether during the last few days the light was at fault, or whether the great heat we have experienced has not affected the developer or the neutral action of the developer and the bath. To me it appears certain that in the negatives I took during the period referred to, the invisible image was on the plate in a fit state to emerge as a clean and brilliant negative, if I had had a proper developer to bring it out; such in fact as the developer I at first accidentally applied, or as the developer I afterwards designedly used a few days old, with the same good effect.—Yours truly,

M. A.

May I ask for an answer to the following photographic queries.

Tannin.

1. Is a bath acidified with nitric acid as good for the tannin process as with acetic? If not, why not?
2. Is an exposure of two minutes with Dallmeyer's triplet, full aperture, i.e., largest diaphragm, long, moderate, or short?
3. Is honey always an accelerator? is it not liable to stain the negative? is not plain tannin the easiest to work? M. A.

[It is well known to experienced operators that an iron developing solution works much better after it has been mixed a few days than when new; the presence of a per-salt having a similar influence to that of an acid in the production of clean shadows. Professional positive portraitists frequently used to mix a Winchester of strong solution months before it was required, and then dilute for use. For negatives we always prefer to have a stock mixed ready for use, especially in hot weather. There is, however, in addition to this a difference in certain samples of the sulphate of iron. A professional portraitist of great experience recently informed us that he was much troubled with thin, fogged negatives for some weeks; the trouble disappeared at once on using a new sample of iron. There is something more to be learned on this subject; but it is certain that an old brown iron solution is a great aid to clean shadows, although it lacks energy in developing at times. When it is not at hand the plentiful use of acetic is the best remedy for the difficulties which troubled you.

In answer to your other queries we may state that as a rule nitric acid is not desirable in a bath for dry plates, from the fact that organic matter is generally used in the preservative, which is apt to be decomposed by nitric acid. For this reason the organic acid is better in such cases. 2. An exposure of two minutes is excessively long for a wet plate and good light with the full aperture of the lens you name. One-fourth of that time or less would generally be long enough. We recently saw some fine negatives of portrait groups with foliage background, by

Col. Stuart Wortley, taken with the full aperture of No. 1 and 2 triple, by Dallmeyer; some of them had received instantaneous exposures, and none more than a few seconds. 3. We believe honey always to accelerate tannin plates; but in some hands simple tannin gives less trouble. See an article by Mr. Fassitt in the present number.—Ed.]

FOGGING NITRATE BATHS.

SIR,—One of your correspondents of last week, J. Bonny, seems to be in the bath fog, where I have often been in days gone by. I have found in my experience, that by making it alkaline with oxide of silver, and sunning it three or four hours, filter well, and drop in a little dilute nitric acid, put to sleep in a dark corner three or four days, I have always found it to work well. It is this resting that is required. If you work it close upon your experiments it will generally fog. If this plan won't cure it, something else is at fault.

I wish some of your correspondents would help me out of Sutton's rapid dry plate fog. I have lately been experimenting on his process, wishing to get a more certain rapid dry process. I cannot succeed yet. I shall try a few more experiments. If I cannot succeed I must go back to the old toning process. I have worked Sutton's gum arabic process, in every form, to a nicety, and have used all his remedies, spoken of in his works, to no purpose. Can you set me right?—I am, Sir, yours respectfully,

JAMES DATE.

Watchet, July 13, 1863.

Talk in the Studio.

DOUBLE SULPHATE DEVELOPER.—A correspondent says:—I have just succeeded in taking some excellent negatives with the developer given in your last by Messrs. Beckett and Willis, and find it quite equal to what they say of it. It also admits great latitude of exposure and will also bear nearly double the exposure actually necessary, which is less than half that required with ordinary iron developer.

THE ATHENÆUM ON PHOTOGRAPHY.—As a critical journal the *Athenæum* has earned the character of being always severe and seldom just; and where photography is concerned, it is often shallowly unappreciative, and for some reason or other, spiteful. We have before had occasion to call attention to scolding paragraphs relating to photography and photographers, and we have before expressed a conviction that, as the gentleman presiding over its pages has opportunities of knowing better, these paragraphs creep in during his absence on summer tours, and are the offspring of incapable and disappointed painters, whose occupation with the palette and pencil is, thanks to photography, quite gone. An amusing specimen of scolding, and of ignorant self-sufficiency recently appeared in its pages, in a notice of "Adjutor," a collection of photographic studies. We had smiled at the paragraph, but did not intend to notice it. We find, however, in our esteemed contemporary, the *Society's Journal*, a few such trenchant comments upon the remarks in question that we cannot refrain from quoting them:—"There are certain writers who, in noticing what is called Compositive Photography, are affected in the same manner that an infuriated bull is on the sight of a red rag; and there is much of the same indiscriminating, unreasoning fury shown in the paragraph on which we are commenting. There is, too, a Dogberry-like tone of scolding, and a priggish dogmatism, which is generally to be found in shallow critics, who make up what is wanting in genuine knowledge by a vehement and extravagant self-assertion. As an instance of this, note the confident, not to say impertinent, tone of this passage:—"Once for all, the "Profession" may take our word that, unless composed with the most subtle art (art of which photography has, as yet, not the dimmest idea), its compositions are, to painters, abominable." Now, whose word is it that we are to take? Probably, some one as ignorant as he is obscure. These anonymous Browns and Joneses, who are allowed to display the capacity of the art-slang vocabulary, and who so cleverly juggle words—not ideas—with a bewildering kaleidoscopic effect, and run as many changes of cant terms as a set of bellringers, assume to themselves an authority, an *ipse dixit* tone, which, to say the least, is simply funny. The patronage of these writers is not less amusing than their wilful, or perhaps more probably still, their absolute, ignorance. This writer says, "As pleasant memoranda of things seen and enjoyed, as suggestions of the unseen

substantialities of art (for we doubt if any one feels awed by a photograph of the pyramids), *photographs are handy.* On reading this, one might almost fancy that the writer of this was one of those miserable brainless daubers whose artistic existence had been happily snuffed out by photography. We really do think that journals professing to hold such high positions as the arbiters of art ought really to be a little more discriminating and catholic in their judgments."

PRESERVATIVE PROCESS.—A correspondent says: "I recently tried Mr. Blanchard's *honey preservative*; so far the results are very satisfactory. I gave 15 seconds exposure with Mr. Dallmeyer's No. 4 triple and a 12 by 10 plate. As Mr. Blanchard remarks, there is a faint blue tint in the sky. The foliage is clear and decidedly rich and full. In my mind more picturesque than in the ordinary wet process. I prepared the plates at 2 and used them at 4½ p.m., a very hot summer day last week."

PHOTOGRAPHY IN THE WITNESS BOX.—In the recent trial arising out of the Roupell forgeries, photography appears to have been frequently used in obtaining *fac-similes* of deeds, signatures, &c. A photographed copy of a deed placed in the hands of a witness under cross-examination was, however, disallowed by the judge as irregular.

MR. POUNCEY'S NEW CARBON PROCESS.—We received a day or two ago from Mr. Pouncey a slip of paper covered all over with printer's ink, and resembling in appearance the transfer paper used in manifold writers. We were informed that it was exposed on the 9th of May last, and were instructed how to develop it. Following the instructions, we immersed the paper in turpentine, and in a few minutes had the satisfaction of seeing a well-defined picture appear, with fine gradation of half tone, and clean lights. We shall have more to say on this subject shortly; but, in the mean time, may remark that so far as we can judge, the process is as simple and satisfactory as it is ingenious.

To Correspondents.

M. P.—As your first print from your first negative, the picture we have received is not had. It is not focussed with sufficient care to secure sharpness: always focus upon the eye. There is no simple method of ascertaining whether collodion is simply iodized or bromo-iodized. Experienced photographers would generally ascertain by the resulting negative. 2. There are many good bromo-iodized collodions in the market, but we cannot speak with certainty as to whether they are all equally suitable for dry plates, as well as wet. Blanchard's collodion is one which we have found answer well for both purposes; as will, doubtless, several others which you will find announced in our advertising pages. Most bromo-iodized collodions will keep a few months, and some longer. 3. We do not know anything of the collodion of the firm to which you refer, nor can we account, without seeing an example, for the odd defect you describe. 4. We know nothing especial of the keeping qualities of No. 1. 5. Most bromo-iodized collodions will answer for positives, as well as negatives. 6. Good positives may be obtained in a negative bath; but, as a rule, more nitric acid is desirable for the positive bath than for the negative bath.

C. W. WALTER.—Take a little emery powder and water, and place on the glass you wish to roughen; then place another plate of glass upon it, and grind the two together until you get the surface required. The rough surface will, of course, slightly interfere with the transparency of the glass, the amount of opacity depending on the coarseness or fineness of the roughed surface.

CALX.—Your negative arrived shivered to some hundreds of pieces, not one large enough to enable us to come to any conclusion upon its character. We are at a loss to suggest a cause for the stains, the nature of which we do not clearly understand. Have you tried another sample of collodion? Does it proceed from over-iodizing?

J. FULLER.—The whites in the print sent are quite as pure as they should be. There ought not to be more than a few minute points of pure white in a picture; a slight amount of detail should be found in white fabrics, like the cap strings in your picture. More pure white would injure the picture.

CONSTANT READER AND AMATEUR.—Try the lime toning bath given in our last. It yields fine black tones.

GEORGE CHIPMAN.—The yellow spot is a hypo stain, caused by hyposulphite of soda, probably on the fingers, touching the print before it was fixed. 2. The silver in old hypo solutions should be precipitated as a sulphide, by means of liver of sulphur, as we have repeatedly described.

A.—The deposit in the shadows which makes the film rise in small blisters when varnished, is generally the result of dirty plates. The tendency will be increased by the use of some samples of collodion; a thin rotten film will aid in producing the defect. The silver in developing solutions will gradually be precipitated in time as a grey metallic powder. Any traces remaining in the supernatant fluid may be precipitated with coumion salt as a chloride.

AN AMATEUR asks will a "carte" lens cover as much as a half-plate lens. That entirely depends upon its length of focus. Some card lenses have a long focus and will cover a half-plate, whilst others have a shorter focus and will not cover more than a quarter-plate. Lenses advertised as card

lenses are generally intended to define a standing figure three inches high, and cover the whole card, and it does not follow that they will cover much more. They are of course suitable for other work as well. The formula of the "Alabastrine Solution" is a trade secret, which we are not at liberty to divulge. Its distinctive characteristic was that it gave white pictures without the disagreeable blue tint. It was sold by Squire and Co.; but since the introduction of card pictures has not been much used, we believe.

PLATO.—The prints appear to have been fixed in an old and acid hypo bath. 2. The exact quantity of hypo required to fix a given number of prints cannot with accuracy be stated; but you will be safe if you use about 2 ounces of hypo in 10 ounces of water for 100 card prints. 3. 25 card prints are not too many prints to tone at once in 10 ounces of water containing 1½ grains of gold, &c., provided they were kept moving, and had constant attention. They would probably tone within a quarter of an hour.

AN AMATEUR SUBSCRIBER.—You used the bath of gold and carbonate of soda too soon after it was mixed; and the negative is not sufficiently vigorous to give good tones. 2. Possibly your bath contained acetic acid, in which case neutralising with carbonate of soda would produce acetate of silver in the bath, which is a frequent source of pin-holes. Sun the bath and filter; then try.

A LOVER OF THE BLACK ART.—We have seen, and ourselves produced, some very good pictures on Dr. Hill Norris' dry plates. But they require great care in keeping and in developing. 2. We cannot say anything about exposure necessary without knowing the subject, state of light, stop to be used, &c. Dallmeyer's compound stereoscopic lens will produce as good portraits as his No. 1 or 2 B, but of course of smaller size. It is, as you anticipate, one of the most rapid lenses made. It is not so well suited for enlarging and copying as the triple.

J. GIBERT.—The formation of metallic silver on the plate during development may be due to various causes, such as the presence of organic matter in the bath, want of sufficient acid in the developer, high temperature, &c.

PERPLEXITY.—We have several times recently had complaints of similar spots; but we have no clue whatever as to the cause. The spots which, in the unfixed print enclosed, showed most at the back, have, after we have toned and fixed it, almost entirely disappeared at the back, and are seen chiefly in looking through the prints. It is most probable that they are produced by something in the paper before it is albumenized, but by what we cannot say. We should like to try a sheet of the paper said to be prone to produce those spots, in order to test it.

T. G.—The chief thing you could do to improve the groups would be to use a smaller stop, and arrange the figures in a curve to suit the lens. In those sent the marginal figures are sharpest; the central figures being a good deal out, whilst the sash a little distance behind the central figures is well defined. You will readily see that if the central figures had been further back, they would have been sharper.

P. G.—You entirely mistake the meaning of the term brilliancy. This is not a brilliant photograph, but a hard one, all black and white, without half-tone. In a brilliant print there is very pure black or white, mere touches, but abundance of gradation. Expose twice as long, and intensify less.

ED. REEVES.—The spot looks like hypo, and occurred most probably after the paper was sensitized. Some samples of paper are more prone to mealiness than others, but slow toning with an old solution is generally the best remedy.

G. E. T.—No especial standard has ever been agreed upon; but we think that about half an inch in the picture for each foot of height in the sitter gives a good idea of proportion. Mounting the print with very little space over head gives the effect of tallness, and with excess of space the effect of shortness.

ESQUIER.—You do not state which formulae you employed: several were given in the article referred to. If you mean the one we especially recommended, it will keep good for weeks without precipitation of the gold, and many, if the prints be properly washed, be used over and over without disadvantage. 2. The spots to which you refer are due to faults in the paper. 3. Always filter any portion of the toning bath returned to the stock bottle.

A YOUNG PHOTOGRAPHER.—We do not know of any photographic art union in existence. Several correspondents in our next.

Photographs Registered during the Past Week.

MR. JAMES MUNRO, 56, St. Peter's Place, Canterbury,
Photograph of Canterbury Cathedral.

PHOTOGRAPHS IN PRINTING INK.

THE production of a photograph direct from the negative, in the very material which has always been regarded as the type of permanency and pictorial stability—printing ink, is unquestionably a master stroke of ingenuity. This has been the result desiderated from the time that silver prints have been found to fade. As carbon process after carbon process has been tried with more or less of success, as one method after another has been suggested for securing permanency in silver prints, it has been the repeated ejaculation, "If we could only get photographs in printers' ink, in the material which gives durability to printed books and engravings!" Mr. Pouncey has solved this problem. Whatever may have been the merits or demerits of his former processes and his former claims, we are bound to state that his present process, just protected by Her Majesty's royal letters patent, is as beautiful and simple as it is ingenious.

The term "photograph in printing ink" is at first sight suggestive of a photo-engraving or a photo-lithograph. But let the term be distinctly understood: by the process to which we refer, a print is produced direct from the negative in printing ink, just exactly as a print, by the ordinary method of printing, is produced in silver. This process does not in any way clash with photo-lithography or photo-engraving, although it may possibly be found a valuable adjunct to both, as a method of getting the image on the stone or plate. At present they are valuable for the rapid reproduction in large numbers of all subjects which can be represented in the conventional gradation of stipple or hatching. Even if half-tone be eventually satisfactorily secured in negatives of all classes, from nature, they will not be put on the stone or plate for production by the printing press, except when large numbers are required. But in Mr. Pouncey's new process he aims at superseding the use of silver for single prints, whether the subject be portrait, landscape, or reproduction.

We have, just before writing these remarks, exposed and developed, in conjunction with Mr. Pouncey, two portrait negatives, one very soft and thin, and the other very dense. The light was one of the worst we have had this summer, misty and yellow, only one degree removed from a fog. This of course interfered with the certainty of our operations, and materially prolonged the exposure. Nevertheless we obtained two good prints. The time of exposure usually required in sunlight with an ordinary good negative, Mr. Pouncey informed us, is about twenty minutes or half an hour. On this occasion we exposed for about two hours; possibly a quarter of an hour longer, in the bad light we had, might have been an advantage.

In the point of weakness, common to most carbon processes, these prints are faultless. The gradation of half-tone is amazingly perfect in every part. Every gradation in the negative appears to be accurately registered. So far as we can see at present, the colour or tone of the prints is the chief point in regard to which we should desire modification.

The material used is, as we have said, printing ink, and the colour of the print is, therefore, gradations of black. Now when these gradations are formed by stippling or hatching, giving a perfect black and perfect white in small points, or fine lines side by side, a variety of agreeable tones of pure grey are produced, varying in depth of tint according to the state of subdivision of the points or lines and spaces. But when the gradation is produced, as we have it here, by gradations of depth in continuous tints of black printing ink like a wash in water-colour painting, the greys appear to have a very slight greenish brown or olive tinge, which we scarcely like. This, it will readily be seen, is, however, a matter entirely under control, the exact colour of the ink being a matter in the hands of the operator, a warmer tint being easily obtainable. Another difficulty which has existed, Mr. Pouncey is just surmounting. We described one of these prints we received some months ago; and we then said that something more was desirable in the purity of the lights or whites. Mr. Pouncey informed us at the time that this was a matter chiefly depending on the quality of the paper. A sample of paper he has recently obtained will, he believes, entirely remedy this difficulty. One of the prints we have just tried is upon it, and shows a considerable improvement upon the former print, and will, probably, leave little to desire. Nevertheless, in points of detail, as to the exact material and tint desirable for different subjects, it is probable that enlarged experience will bring improvements.

Now as to the process. In another column we publish the specification of the patent; but it may, nevertheless, be interesting to give a brief summary of the manipulations, and the principle upon which they are based, here. It is somewhat singular that upon two of the oldest facts in photography this process is founded: upon the fact that bitumen of Judæa becomes insoluble in its ordinary solvents when exposed to the action of light—a fact known to Niepce as early as 1827, if not earlier to some of our own savans; and upon the fact that bichromates, in combination with organic matter, become insoluble under the action of light, a fact discovered by Mr. Monge Ponton, in 1838. Almost every carbon process and method of photo-lithography and photo-engraving yet propounded has been based upon one or the other of the facts we have just mentioned.

The merit of Mr. Pouncey's process consists in the novel and ingenious application of known facts, and in further development of these facts. The properties of bichromates and of bitumen of Judæa were known, but it was not known that these substances might be so incorporated, or combined, with ordinary printing ink that it should become insoluble after exposure to light. This is what he discovers. In many respects his new carbon process resembles others. He takes lamp-black or other carbonaceous pigment—a fatty matter, such as tallow and turpentine—the materials composing printing ink; to these he adds bitumen of Judæa, or bichromate of potash, or both; these materials are ground together, and thoroughly incorporated. The pro-

portions are varied with circumstances; generally, as much pigment is added as will make the mixture the consistency of cream, and as much of the bichromate as will remain in the solution, which is a very small proportion, as it is very sparingly soluble in turpentine. A suitable paper is first slightly sized with gelatine, and when dry, brushed over with the preparation of printing ink, and then dried. The paper so prepared, and kept in the dark, will remain ready for use without deterioration for an indefinite period, some months certainly.

This blackened paper, when placed under a negative and exposed to light, undergoes the change to which we have referred: the parts of the ink on which light acts become insoluble, whilst the protected parts remain, as at first, soluble in turpentine, benzole, &c.; and, what is singular, the amount of insolubility is in sufficient gradation to leave on the paper just the proportion of ink which shall register every variety of tone in the negative. And here is to be noted another valuable little point of detail in the manipulations. As we have already remarked, the weak place of most carbon processes hitherto has been the difficulty of securing half-tone. This was largely overcome by M. Fargier's modification. He rightly conceived that one source of the difficulty lay in the fact, that as the action of light commenced at the surface of the layer of gelatine, bichromate, and carbon, spread on paper, it only penetrated *through* the most transparent parts of the negative constituting the deepest shades. The parts constituting the half-tone were only acted upon superficially, the part in immediate contact with the paper being unacted upon, was, therefore, readily dissolved entirely off, and the result was a print with hard black and white tones, without perfect gradation. He, therefore, coated the exposed layer of gelatine, &c., which was used on glass instead of paper, with collodion, and immersed the plate in water, which detached the film; the unaltered gelatine, &c., was then washed away from the underneath side. By this contact with the collodion every part acted upon by light was preserved, and half-tone secured. Mr. Pouncy, possibly without having noticed the coincidence, acts upon a similar principle. He uses a fine, thin wove paper, of the quality known as bank post. This is made transparent before it is coated with printing ink, and the printing is effected *through* the paper. The inked side never comes into contact with the negative, but the plain side of the paper. How far half-tone would be secured if the inked side were printed on, we cannot, with certainty, say, but we have no doubt that the method of printing through the paper, and thus securing the first action on those parts in immediate contact with the paper, must materially tend to secure half-tone. For this reason, whenever the slightest action takes place, a thin film of ink in immediate contact with the paper is rendered insoluble. All but that thin layer will be subsequently dissolved and removed, but the half-tone remains. The transparent parts of the negative permit the full action of light to penetrate the entire thickness of the layer of ink, and thus the deep shadows retain a full body of insoluble ink, and are the blackest portions. On slight reflection it will be readily seen, then, how this mode of printing through the paper conduces to the production of half-tone; and this is our explanation of the great superiority of these prints in this particular. Whether Mr. Pouncy holds the same view, or whether his practice may confirm it, we do not know, as we did not enter into theoretical considerations in our interview.

The proper exposure may be learned by experience, or by the exposure side by side with the negative of a trial piece of paper. Being black to begin with, examination affords no clue to the process of printing. When the exposure is completed, the print is immersed in a dish of turpentine, which dissolving the ink which is not acted upon, and removing it, reveals the image, consisting of the gradations of insoluble ink. After draining a few minutes, the print is removed to another dish of clean turpentine, which effec-

tually clears the lights and finishes the print. It is now laid on blotting paper, a strip of which is placed at the bottom edge to absorb drainings, and then dried in the sun. Care must be taken not to touch the face during the operations, for whilst the ink is not acted on by a solvent, it is easily smeared until it is dry. Other solvents than turpentine might be used, but turpentine appears to answer best. It may be used over and over, merely using each time a little fresh, to remove the final traces of soluble ink and secure purity. Nothing can be more interesting than to witness the completeness with which every trace of the ink leaves the whites in the most perfect purity. With turpentine there appears to be no danger of injuring the print, however long its action may be continued, not even a trace of half-tone being dissolved. But with a stronger solvent, such as benzole, for instance, great care is necessary, its prolonged action impoverishing the print. Where the operations are sufficiently extensive to make the cost of turpentine a consideration, it is probable that it might be utilized for some purposes where the ink it had collected whilst in use would not be objectionable, as, for instance, in black paint. As the price of turpentine has for some time been high, costing now, we believe, about eight shillings a gallon, this might become a matter worthy of consideration.

The lights of the cleansed prints, on the most satisfactory paper, are quite transparent, becoming white, of course, when mounted. A slight tint might easily be secured, in subjects needing it, by mounting on a tinted paper. Mr. Pouncy recommends varnishing the prints, first with a spirit varnish, and then with the usual varnish applied to maps, prints, &c. We are inclined to think that this will not be necessary, and will be in some instances objectionable. With the sample of paper we have referred to as most successful, the print may be mounted face downwards, the print showing perfectly at either side. For some experiments ordinary tracing paper has been used, which answers very well, but not so perfectly as the sample to which we have just referred.

It will be seen that, apart from the question of cost, an immense saving being effected by dispensing with silver and gold; apart from the question of permanency, the greatest question of all, there is a great saving of time in absolute manipulation. The removal of the ink is an operation about equivalent, in its demands upon time, to toning. There is then no fixing, and no interminable washing; the print is completed.

As will be seen from the specification, there are various other very important economic applications of the process. A transfer, with perfect half-tone, may be made to copper, stone, or zinc. It may be made an adjunct to an enamel process. It will, probably, become very extensively used in ornamentation. We see a most important position for it in photographic printing on earthenware and china, as a transfer exactly similar to that now used in the potteries, but with photographic image, may be without difficulty produced. Various other uses may also follow, which we need not glance at now.

We have given a simple, unvarnished, and unexaggerated sketch of the process and its results, avoiding everything like enthusiastic epithet, feeling that, having reference to the past, we best serve our readers and Mr. Pouncy by doing so. We have, nevertheless, been very highly delighted with what we have seen and produced; and, if all our anticipations and hopes in connection with the subject are fulfilled, it will prove one of the most important steps yet secured in the progress of the art.

We should add, in conclusion, that Mr. Pouncy's arrangements in connection with his patent appear to us to be liberal. He is arranging to supply the prepared paper, ready for exposure, to any one at about a guinea a quire, so that amateurs will be able to experiment without a license. To professional photographers, wishing to use the process for commercial purposes, he intends to supply an annual licence for five guineas. To professional printers this amount will

be a very unimportant consideration, if the process turn out as successful in general practical operation as it has done in our hands.

PHOTO-ENGRAVING.

THE vast economic value of a thoroughly good and simple method of photographic engraving can scarcely be over-estimated, and from the earliest history of photography efforts have been made, with more or less of success, to secure such a process. Most of our readers are familiar with the various methods attempted, from Fizeau's process of etching Daguerreotype plates down to a recent date. Whilst recently in Paris we saw specimens, apparently of much promise, of two new processes of photographic engraving, the details of which, however, were not stated. A month or two ago we were favoured by a visit from M. De la Blanchere, who showed us a number of exceedingly fine proofs from plates produced by his "heliographic machine." They consisted of portraits, about 10 by 8, of public men popular in France, from fine negatives by Nadar. As pictures and portraits they are exceedingly fine—bold and artistic, and, at the same time, full of photographic half-tone. They are, we are assured by M. De la Blanchere, entirely untouched. At the same time, they bear throughout the marks of a tool sufficient to induce at the first glance a doubt of this statement. These markings of the tool are, however, probably due to the treatment of the plate by the method adopted by mezzo-tint engravers, and they are doubtless really untouched, so far as that term is meant to imply that the plates are not worked upon by the engraver, and that they owe nothing to the hand of man. A bitumen process is employed in obtaining the plate, and the whole result, which is very fine indeed, is, we are assured, due to the action of light and the "heliographic machine."

The best example of photo-engraving which we have yet seen, however, is by a process invented by Mr. D. C. Dallas, a gentleman who was associated at one time—to his cost, as he informs us—with the Photo-galvanographic Company, which came to grief some years ago. A specimen before us, "Kenilworth Banqueting Hall," from a negative taken expressly for the purpose by Mr. Bedford, is, we are assured—and the print bears evidence to the fact—from an entirely untouched plate. It has excellent gradation of half-tone, and is bold and vigorous. A few touches by a skilled engraver would make it a perfect picture. We have it here exactly as produced by chemical action, in order to illustrate the capabilities of the process.

We regret that, owing to the unsatisfactory protection afforded by the existing Patent Laws, Mr. Dallas, at present, does not perceive any method of reimbursing himself for the cost—some thousands of pounds—of his initiatory labours, except in keeping the working and secret of his process in his own hands. We subjoin his communication on the subject:—

In consequence of the very questionable protection afforded by the Patent Laws, I deem it advisable at present not to publish the details of my process. I have already sacrificed much to the "idea" of engraving photographs, and as I believe I have now solved the problem in a satisfactory manner, I am naturally anxious to remunerate myself. At a future time I may make a proposal the effect of which, if agreed to, will be to enable others to work my process.

From the encomiums passed by highly qualified judges on the specimen I now submit—Kenilworth Banqueting Hall, from a photograph by Bedford—I think I am warranted in saying that I have solved the problem of successfully engraving photographs. But I should not consider myself entitled to the merit of this discovery were the specimen above mentioned touched up by the graver, or even the result of a happy chance. I am glad to be in a position to say that the specimen has only required careful cleaning, and that unless my head and my hands fail me the result is certain. I can guarantee to produce, in a period varying from one to three weeks, an engraved plate from a photograph. In this plate, that which constitutes the

essence of the photograph and the despair of hand labour—*fac-simile* even to minute and almost microscopic detail—shall be present. To attain this result, all that I require is a good reversed negative (easily produced by reversing the glass), and a positive print merely fixed with hypos, not toned.

The methods which have hitherto given most promise are the bitumen process, photoglyphy, and photogalvanography. The other processes of photolithography and photozincography, from their very nature, cannot rival the richness of plate printing. The bitumen process and photoglyphy are essentially etching processes, and involve much hand labour and consequent loss of fidelity. Photoglyphy is the least satisfactory of the two, as the etching ground employed is of a very delicate nature, and the photographic chemical, bichromate of potash, has the unfortunate quality of destroying detail, the longer it is submitted to actinic influence.

The most important step in advance was photogalvanography. This process came into my hands when in a most crude and impracticable condition, and after it had been given up as useless by others. By much patient labour I succeeded in making it practical, and the process has ever since been worked with the improvements which I effected. I was not permitted to reap the fruit of my labours, and after a considerable sum had been expended, by my then partners, to develop the process in a direction to which it was wholly unsuitable, the process has been almost abandoned.

Photogalvanography, like photoglyphy, depends on the peculiar action of bichromate of potash, in combination with gelatine. In this lies its weakness. It loses detail—the more so as it requires a very long exposure, sometimes upwards of six hours, and then without any certainty that the right exposure has been attained. There are consequently numerous failures from this one cause alone.

I experimented long with this process, and found that the result was due to chromic acid. In other words, that with a composition merely of chromic acid and gelatine, a raised image with granulation could be produced. From this raised image the electrotype plate was subsequently made. Independently of the loss of detail, and the uncertainty in the exposure—both defects inherent in the process—the granulation was of a peculiar zig-zag and wiry character, which was of great value in the vigorous parts of the picture, but became broken or unconnected in the half-tones and fine details. This led to a pretty free employment of the graver and roulette, just in the very parts which made hand labour expensive. The process, indeed, was never capable of the high flight which was attempted, and, as I predicted, it broke down. Where expense was no object, the graver was a great assistance, but it lessened the value of the *fac-simile*.

In photoglyphy and photogalvanography, the results are obtained from a positive impression.

It was after experimenting some time with photogalvanography that it occurred to me to strike out in a different direction. Any one acquainted with engraving is aware that aqua-tint and "chalk," or stippling, produce fine grain, half tones, and detail. The problem I set myself was, how to imitate this combination. The aqua-tinter employs common resin dissolved in spirits of wine. This poured over his plate evaporates, and leaves numerous globules of resin attached to the surface. The size of these globules depends on the proportion of resin to spirit. When the acid is put on the plate the resin acts as a resist, and a tint is produced in the intermediate parts. If the plate were now electrotyped before the removal of the resin, and a print taken from the electrotype, the resin parts would give a kind of stipple or "chalk" marks, interspersed with tint. It is something similar to this which I have succeeded in imitating, with peculiarities *sui generis*, by photoglyphy and the electrotype. I can also, as it were, modify the size of the dots, obtaining them so fine as to carry almost microscopic detail; but if too fine there will be deficient depth in the dark. In this as in all things there is the happy medium, and this I believe I have secured. I commence with the negative. This should be reversed. From the negative a positive proof is taken; this I prefer not toned, but merely fixed in the sepia colour by the "hypos." I cover the negative, which must be varnished with a material from which I obtain a latent positive. This latent positive I turn by a simple process into a suitable negative, and it is with this negative that I subsequently manipulate. I can time the exposure to a nicety, a few seconds over or under making an inappreciable difference. The excess or deficiency must not, however, extend to minutes

If necessary, I can electrotype direct upon my material; but as this might lead to the discovery of part of my process, I prefer to make a different kind of matrix.

I should have been glad to have taken out a patent, in order to grant licences, but as the lawyers say no patent is valid till well litigated, I prefer to run the risk of competition, which after all is of more benefit to the Arts than monopolies such as the present Patent Laws permit.

THE DIFFICULTIES OF LIME TONING.

BY JABEZ HUGHES.

IN last week's NEWS appeared a letter signed "Cha-meal-ion," written apparently "half in joke but all in earnest," complaining of the difficulties encountered in using a lime toning bath. I cannot say I am surprised at the narration of failures, as I know from experience how difficult it is to work a lime toning bath without meanness. As "Cha-meal-ion" is evidently a person of intelligence and experience, there must be some weak point, though glancing at what has been written on the subject I cannot detect it. Meanness, however, is not peculiar to the lime toning baths, though it certainly has a greater tendency to be shown with their use. For this reason I do not think the lime toning process will ever be in general use. I have practised this process for a considerable time, and have had the opportunity of seeing it worked out by my several assistants. I have been at some times elated with the beautiful result, and at others depressed with the miserable failures; and the general conclusion I draw is, that more pains and skill are required to produce good results with it than with the usual ones containing acetate, phosphate, or carbonate of soda. "Cha-meal-ion" may rest assured that others have had their failures as well as himself, but few have so flaukly and jocosely proclaimed them.

I do not think that any of the toning baths depend for their proper working on such delicate conditions as this chloride of lime one. When I first purchased the late Mr. Lacy's business I found a German printer there using the lime toning; and, keeping a photographic depôt and selling albumenized paper, as I did, I naturally wished to introduce my own wares, but the printer told me "dere vas only von kind of baper dat vould do, and I must have dat." Many quires of paper were found on the premises, good paper for other toning processes, but I was told that "it had all been dried, and vos bad; it did not suit the doning bath." When I proposed to print in another house I alarmed the printer, who exclaimed, "I must have de same water; dere is only von vater dat vill do vor de briuting, 'specially vor de doning bath." In this manner I was introduced to the peculiar conditions under which the lime toning bath could be successfully worked.

It would scarcely be necessary to give "Cha-meal-ion" a fresh formula, after he has failed in those already published, or I might refer him to the new edition of my Manual, in which the subject is discussed, but the truth is that there cannot ever be a complete formula, because the minor modifying causes cannot be embraced. Let "Cha-meal-ion," however, try and work out a formula for himself. Let him take two solutions; one of saturated solution of carbonate of lime, say three ounces, and one of saturated solution of chloride of lime, say two ounces. Mix these two solutions in the proportions given, and add forty-five minims of the mixture to one grain of chloride of gold in solution. This bath, diluted to, say, eight ounces of water, may be used immediately, but will be better for waiting twenty-four hours. Wash the prints as usual, and tone them. If they are mealy, reduce the proportion of the chloride of lime, or increase the proportion of carbonate of lime. If the prints are not mealy, but refuse to take a black tone and become blue, increase the chloride of lime until the black tones are obtained. If too much chloride of lime is used, meanness is set up instantly, before toning even begins. Upon the harmonious proportion of the chloride of gold, chloride of

lime, carbonate of lime, the amount of free hydrochloric acid in the gold solution, as well as the nature of the albumenized paper, depends the tone of the print. It will thus be seen that a formula that succeeds in one person's hands may easily fail in another's. The so-called saturated solution of chloride of lime may, in "Cha-meal-ion's" case, contain more or less than in mine; the same with the carbonate; and the acidity of the gold solution will be quite variable, to say nothing of the nature of the paper. Can it be surprising, then, that a "Cha-meal-ion" may fail where an Ommegeanck succeeds? The Parkinson formula is one that he worked out himself from the Ommegeanck; he does not pledge himself it will succeed with others, he only knows it is just the thing for himself. The formula I have proposed for "Cha-meal-ion" to start with is successful with me just now, but next week, if I open a fresh ream, I may find the new paper requires a variation of the toning bath to suit it.

To conclude, I would urge on "Cha-meal-ion" and others who may wish to try the lime toning, that they must make a liberal allowance, in following the formulae of others, for those minor circumstances that influence the result—that they must trust rather to the general spirit of the instructions than the precise details.

I trust that "Cha-meal-ion" may find some of the hints given to be useful, and as a proof that clear and brilliant prints without any meanness can be produced by the lime toning, I enclose a few.

Ryde, I. W.

PHOTOGRAPHIC CHEMICALS:

THEIR MANUFACTURE, ADULTERATION, AND ANALYSIS.

If it is desired to obtain pure manganate of potash in the crystalline form from *mineral chameleon*, it is dissolved in a small quantity of pure water, the solution decanted from a little sesquioxide of manganese which may be deposited, and evaporated over oil of vitriol under the receiver of an air pump. Green crystals will be deposited, which are the salt in question. These crystals are decomposed by water, yielding a red solution of permanganate of potash and brown peroxide of manganese, caustic potash being separated at the same time. The formula for this decomposition being as follows:—

When free potash is present the decomposition is not so rapid, and hence, when the crude substance is dissolved in a large quantity of water, the decomposition taking place gradually causes the liquid to assume various colours. The solution is dark green at first, but rapidly changes through blue, violet, and purple, to carmine red, in proportion as the excess of potash is removed from the salt by the water, and by the carbonic acid of the air. The changes occur with greater rapidity if the water be in large excess, or if it be hot.

Permanganate of potash is always prepared from the manganate, by making use of the reaction shown in the above equation. This salt can be purchased at most chemists', both in solution and in the crystalline form; but as some of our readers may wish to prepare it for themselves, we give the process which we have found most effectual; it is the one originally recommended by Gregory. Add to a finely divided mixture of 8 parts of peroxide of manganese and 7 parts of chlorate of potash, a solution of 10 parts of hydrate of potash in a very small quantity of water; evaporate to dryness, during which a small quantity of mineral chameleon is formed; ignite the finely pounded mass in a crucible till the whole of the chlorate of potash is decomposed (for which a low, red heat is quite sufficient); reduce the semi-fused mass to coarse powder, and boil it in several times its weight of water. An insoluble deposit will be formed, which allow to subside and separate by decantation. Evaporate the clear solution rapidly, during which time a

fresh precipitation of peroxide of manganese will be precipitated. Separate this by decantation, and leave the solution to crystallize by cooling. When all the crystals have deposited, pour the supernatant liquid off, and wash the crystals with a small quantity of cold water; dissolve them in the smallest possible quantity of boiling water, and leave the solution to crystallize on cooling. In this manner needles are obtained three-quarters of an inch in length, and amounting in weight to about a third of the peroxide of manganese employed. In order to avoid the unavoidable losses arising from decanting the solutions, they may be filtered, employing a funnel having its neck stopped with asbestos. Permanganate of potash crystallizes in dark purple needles having a sweetish taste; it does not alter the colour of test papers, and is not deliquescent. When heated, the crystals decrepitate, evolving oxygen. As might be supposed from the great amount of oxygen they contain, friction in a mortar with substances greedy of oxygen, such as phosphorus, sulphur, &c., produces detonation. Permanganate of potash dissolves in 16 parts of water at the common temperature, forming a purple solution. When potash is added, this colour changes, through violet and blue, to green. When ammonia is added to the solution, its hydrogen is oxidized with precipitation of peroxide of manganese. All organic substances exert a deoxidizing action on the solution. Alcohol acts with peculiar rapidity; gum, sugar, paper (as, for instance, when used to filter the solution) act more slowly. Decolorization also takes place when the liquid is exposed in open vessels, organic particles falling into it from the air, and carbonic acid at the same time combining with the potash. In purifying water by means of permanganate of potash, Mr. Condy has pointed out that not only is organic matter removed, but lead is also separated. Every one knows how deleterious, but, unfortunately, how common an ingredient this metal is in water after being stored in lead cisterns. When permanganate of potash is added to water containing oxide of lead in solution, it gives the metal an additional equivalent of oxygen, converting it into binoxide of lead, an insoluble brown powder. In a similar way, iron may be separated from water.

The method of testing and purifying water from organic impurities is very simple. Prepare a solution of 10 grains of permanganate of potash in one ounce of distilled water. Take a tumbler of the water to be tested, and add to it, drop by drop, the permanganate solution, until the pink colour which it communicates to the liquid does not disappear on standing. If the water be perfectly pure and free from organic matter, the first drop will produce a permanent pink tinge throughout the whole of the liquid, which no amount of standing will cause to disappear. If common distilled water be used containing the usual amount of organic matter, the colouration produced by the first drop will disappear in the course of five or ten minutes, and a brown turbidity will be visible in the liquid. Generally speaking, another drop will be required to render the pink colour permanent. A very good means of comparing the qualities of various waters in respect to their organic impurities is to arrange a series of glasses side by side, each containing a certain quantity, say 10 ounces, of the water, and to add one drop of the permanganate solution to each in rotation, repeating the addition at intervals of five minutes. The number of drops required to be added before the pink tinge becomes permanent will be a very good measure of the relative amounts of organic matter present. In employing this process for purifying water in quantity sufficient to employ for photographic operations, the permanganate can be added directly to the water contained in a stone vessel or cistern. An ounce or so of the solution of permanganate may be added at a time, and the water may be stirred up with a glass or china rod. A quarter of an hour should be allowed to elapse between each addition of permanganate solution. When the decolorization of the pink water proceeds with difficulty it is a sign that the point of purification is nearly

reached, and the addition of the pink liquid may then proceed cautiously, half or a quarter of an ounce at a time. So long as decolorization takes place more permanganate should be added, and the water should eventually have a very slight excess of pink tinge in it. If this purification is employed on a small scale, say one or two gallons only, it can be allowed to remain at rest for a few hours, and then be filtered through clean white filtering paper. This effects two objects. It separates mechanically the precipitated peroxide of manganese and other impurities which may have been deposited during the act of purification, and it also removes the last trace of permanganic acid which has purposely been added in excess. If the purification has taken place in a cistern, the deposit may simply be allowed to subside, and the clear liquid can be drawn off. If exposed to the air the pink colour will gradually disappear in a day or two, or it may be at once removed by putting a few lumps of freshly burnt charcoal into the water. For all photographic purposes water so purified (except it contains an unusual proportion of earthy or saline impurities) is better than the common run of distilled water; the small amount of potash salts introduced in the process of purification being unimportant in comparison with the large quantity of injurious matter separated.

Critical Notices.

THE PRINCE CONSORT MEMORIAL. PHOTOGRAPHED BY DR. DIAMOND.

WE are uncertain at the moment we write whether these photographs are intended for publication or for private circulation only. If the latter, it is, we think, matter for regret, as they afford the only means by which the majority of those interested can become acquainted with one of the noblest works in monumental sculpture which this or any country possesses. The fact that a commemorative memorial, combining the double aspects of a record of the first Great Exhibition, and a tribute to the late Prince Consort, with whose memory that Exhibition will ever be associated, should be erected in what is virtually a private garden, belonging to the Royal Horticultural Society, is matter for general regret, the greater that its chief attractions consist in a series of sculptures which go far to redeem us from the national reproach of inferiority which has attached to so much of our public statuary.

The memorial, which is of red and grey granite, is in the general form of a temple, with the base projecting at the four corners, so as to carry four colossal bronze figures representing Europe, Asia, Africa, and America. The whole is surmounted by a colossal statue in bronze of the Prince Consort in the costume of the Master of the Order of the Bath. The figures are by Mr. Joseph Durham, whose original design—which has, however, undergone some modification—was selected from amongst those of about fifty competitors. Nothing can exceed the grandeur of these allegorical figures, which are treated with a freshness and power altogether unlike the old conventional types. America, for instance, is no longer the Red Indian maiden attired as a huntress, but a female figure of European type, at once beautiful and powerful, resting her arm upon the axe which clears the forest to prepare for the progress of civilization. In all the figures there is manifested a careful study of ethnological types, and a rare feeling of the minute as well as the great elements of symbolical expression. Altogether, apart from the powerful individualism and poetically representative character of each figure, they are very fine as sculptures, the masses grand and simple, yet perfect in every detail of artistic truth and finish. Photographers may be proud to claim in Mr. Durham a member of the council of the Photographic Society.

To those who are fortunate enough to be familiar with the photographs of Dr. Diamond, it will be quite sufficient to

say that these pictures are worthy of him. They consist of whole plate views of each of the five large figures, and one of the same size of the complete memorial. Notwithstanding the difficulty of perfectly rendering bronze figures, owing to their non-actinic colour, these are soft, brilliant, round, and perfectly well modelled, doing justice to the simple grandeur of Mr. Durham's noble sculptures.

PHOTOGRAPHS TAKEN AT SANDRINGHAM. By THE LONDON STEREOSCOPIC AND PHOTOGRAPHIC COMPANY.

To make good pictures out of unpicturesque subjects is a task more difficult than making bricks without straw. All that could be done for Sandringham in the shape of good photography and well chosen positions, has been done, however, by Mr. England and the staff of operators sent down by the Stereoscopic Company. The result is some really pleasing pictures of the hall and grounds, and surrounding neighbourhood, both in stereoscopic and 10 by 8 pictures. In the production of portraits the task was easier. The Princess, always graceful and charming—the Prince, always pleasant, easy, and a gentleman, make good pictures in any style; and of the score of different positions, &c., produced by the company, there is not one bad. A group of the Prince and Princess, the latter sitting on a rustic garden-seat, and the Prince leaning against it, forms at once as pleasing a picture and satisfactory likenesses as have yet been produced. This picture is published both in stereoscopic size and as a vignettted 10 by 8 picture for framing. All the portraits are good, but the group is a gem. We perceive that the company has recently devoted some attention to the production of neat, cheap frames for photographs, which are worth the attention of photographers.

PRIZE PICTURES. By MEMBERS OF THE AMATEUR PHOTOGRAPHIC ASSOCIATION.

All the prize pictures of the Amateur Association are this year good, most of them possessing pictorial as well as photographic merit. If we were disposed to be hypercritical, we should again be inclined to question on what ground the degrees of merit were decided, as there is an equality of excellence in all the pictures, which renders it difficult to say whether those taking the fourth prize are not in all respects equal to those taking the first. The "Hall of Columns," at Carnac, by Mr. Remington, for instance, which takes a fourth prize, is, of its kind, perfect; and "Hill and Tank," an Indian picture, by Lieut. Impey, also taking a fourth prize, would be, were it not for its stopped-out sky, perhaps the most meritorious picture of all. Mr. A. Henderson's instantaneous photo, "The Mountain Maid," a charming whole-plate vignettted picture of a steamer on a Canadian lake, with water, distant foliage, and clouds, all well made out, takes a third prize. The second prize is awarded to a pair of whole-plate subject pictures, "Going a Milking," and "Been a Milking," in which skilful use is made of a few real rustic accessories, giving *vraisemblance* to the general effect produced by a painted background. The composition is good, and the photography excellent; but we should have liked to have seen less consciousness in the model, and different scenery, or the same scene from a different point, instead of the same painted background in the same position in each. The two first prizes are carried off by Mr. Baynham Jones and Major Gresley; the first, for a picture containing much poetry, although not a perfect photograph, called "A Misty Morning;" and the second, for a pair of excellent photographs entitled "Sunshine" and "Shade:" both the photographs are good; but there is not sufficient of the characteristics of sunshine and shade in the pictures to justify the titles. We think, altogether, the pictures are an advance upon those of last year.

SPECTRA OF THE STARS.*

At the meeting of the Royal Astronomical Society held in April last, the Astronomer Royal gave an oral account, illustrated by drawings, of the apparatus which had been prepared at the Royal Observatory, Greenwich, for the observation of the spectra of stars, and of some of the principal results obtained. In the drawing below, the first

figure represents the entire apparatus, in section; the second and third figures represent the right-hand portion of the apparatus in a section through the axis of the long tube, but at right angles to the former section.

In Fig. 1 the smaller tube at the right hand is for insertion in the socket upon the breech-piece of the telescope of the great equatorial. To carry the apparatus steadily (great accuracy of position is not needed), a temporary frame is screwed to the sides of the telescope tube. The right-hand tube is thrust into the socket so far that the image of the star is formed in the moderately small hole in the inner end of that smaller tube. The pencil of light from the object-glass, which has converged to form the image of the star, then diverges and falls in a wide and divergent state upon the prism; after emergence it is received on a combination of lenses, which causes the pencils for the different colours to converge. It is seen thus that a spectrum may be formed at the place of the micrometer; it is necessary now to explain how breadth is given to the spectrum.

For this purpose the prism is not placed in the position of minimum deviation, or the position in which the angles of incidence and emergence are equal. It is so inclined that the angle of emergence is greater than the angle of incidence. With this arrangement, the change in the degree of divergence of the extreme rays of the pencil is different as regards (on the one hand) rays in the upper and lower parts of the pencil, or in the plane of the paper, and (on the other hand) rays in the plane perpendicular to the paper. The difference is such that, when after passing through the lenses the former have converged so as to form a pure spectrum at the place of the micrometer, the latter have passed convergence, and therefore the spectrum has breadth. The position of the prism, which gave a convenient breadth to the spectrum, was determined by trial. It is necessary to remark that the lenses must not be achromatic; they are, in fact, made of dispersive flint glass; if achromatic, the spectrum would have been formed in a plane inclined to the plane of the micrometer. The whole of these peculiarities were calculated numerically on geometrical theory before the construction was attempted.

This principle may be regarded at present as experimental. In simplicity of construction it is much superior to the principle of causing the pencils which pass through the prism to consist of parallel rays, which requires the use of two achromatic object-glasses and one cylindrical lens; but it is not yet certain whether or not it defines the spectral lines with equal sharpness.

It is necessary now to explain how reference is made to the lines of the solar spectrum. In fig. 1, near the right-hand extremity of the large tube, a small circle may be seen. This is a view (not properly in section) of a small socket, which in fig. 3, lower side, may be seen empty, and

* Monthly Notices of the Royal Astronomical Society.

which in fig. 2 contains a small eye-piece. It is thus used. A tube, containing at its end a very small hole (possibly $\frac{1}{10}$ inch in diameter) is thrust, in a definite position, into the right-hand tube of fig. 1, till the small hole is in the focal plane of the telescope image. In this state the telescope is turned to the sun; the small hole represents a star of solar matter; and its spectrum may be observed and measured. An eye-piece with diagonal reflector, and carrying a wire in its focus, is thrust into the small socket, as in fig. 2, and the position of the solar hole with reference to the wire is carefully observed. Then, when a star is to be observed, the small eye-piece is thrust in, the telescope is moved till the star's image has the same position in regard to the wire which the solar hole had, and then it is certain that the star occupies precisely the place of the solar hole; then the small eye-piece is withdrawn, and the spectrum is observed, and measures are made with the micrometer.

For reading the comb of the micrometer there is an annular reflector to illuminate the field, not shown in the drawing.

The following sketch exhibits lines whose positions have been measured by Mr. Carpenter; numerous lines have been seen, but not measured.

	A	a	B	C	D	E	b	F	G	H
Sun										
α Orionis										
μ Geminorum										
α Ceti										
δ Virginis										
Sirius										
Castor										
Procyon										
γ Geminorum										
β Aurigæ										
Regulus										
θ Aurigæ										
Spica										
γ Virginis										
Capella										
β Leonis										
Aldebaran										
Arcturus										
β Tauri										
Pollux										

On this sketch Mr. Carpenter remarks:—

This diagram is only intended to show the positions of the lines; no attempt has been made to illustrate their characters or their different intensities. The stellar lines are generally nebulous, resembling the solar line H; in the

first four stars on the diagram they are, however, much more diffused on the side opposite to the red end of the spectrum.

Since these observations were communicated to the Society, two more lines have been detected in the spectrum of *Arcturus*; one coincident with solar D, the other between it and solar C.

G. B. A.

MR. POUNCY'S NEW PATENT PROCESS FOR PERMANENT PRINTING.

(Specification.)

My said invention relates to certain improvements in obtaining, transferring, and printing from photographic and any other pictures or images, and also in preparing the materials for such processes; the main or principal feature of my invention consisting in the employment of a sensitive or sensitized ink or composition on which pictures or images may be produced by the agency of light, and which may be transferred or printed from in the manner hereinafter mentioned.

The surfaces employed for the reception of the pictures or images may be paper, silk, linen, cotton, or mixed fabrics, leather, wood, ivory, glass, porcelain or stone, or surfaces of metal or of metallic alloys may be used, or any other surface. The surface proposed to be employed is coated with an ink or composition consisting of carbonaceous or other colouring matter (according to the colour or tint of the picture desired to be produced), fat, tallow, or oil, bichromate of potash or bitumen of Judæa, or both of such last-mentioned substances, and benzole, turpentine, or other hydrocarbon or analogous spirit. The respective proportions of the several ingredients hereinbefore mentioned will vary with the circumstances attending the operation.

The mode of compounding such ingredients, and the necessary proportions thereof, will be well understood by persons conversant with the preparation of similar or analogous inks or compositions, with the addition of the two last mentioned substances dissolved in either of the spirits before named. I may mention, however, that if the photographic picture or image is to be transferred on to stone or any other surface suitable for being printed from, a larger quantity of oil or fatty matter is employed in preparing the ink or sensitive composition than when the picture or image is simply taken on paper or any other surface, and is to be used merely in that form. The ink or composition must be prepared and applied to the surface of the material employed in the dark, or in a place from which the actinic rays of light have been excluded, or by an artificial light which does not act photographically. The coated surface is to be dried and excluded from the light until it is about to be used, when a photographic picture or image may be produced thereon by any of the usual and known methods applicable to the purpose.

When the picture or image is to be produced by means of a negative picture or image applied to the sensitized surface prepared as aforesaid, and the substance or material is sufficiently transparent to allow the rays of light to act through the same, the negative picture or image may be placed on the uncoated surface and the light applied so as to act on the coating through the transparent substance or material.

The rays of light having hardened the parts required, and produced the desired effect on the sensitized coating, the parts not acted on thereby remaining soluble are then washed off with benzole, turpentine, naphtha, or other hydrocarbon solvent. The picture or image will thus be left upon the surface employed in printing-ink, or in a composition in the nature of or analogous to printing-ink, and from which impressions can be obtained as hereinafter mentioned.

The pictures or images obtained in the manner hereinbefore mentioned are applicable to a great variety of purposes, both useful and ornamental. They may be preserved simply as works of art, or they may be transferred (if a suitable material for receiving the sensitive coating has been employed) to the surface of porcelain or other ceramic manufactures, and "burnt in" or permanently imparted thereto, according to the well-known methods of performing such operations.

When the sensitive ink or composition is applied to a lithographic stone, for the purpose of printing therefrom, the surface of the stone must be "grained" before the application of

the ink or composition, and the surface of the coating should be also "grained" after it has been laid on the surface of the stone. The process of "graining" is well understood, and, therefore, I need not describe the same. Before transferring the picture to the stone, the surface thereof should be moistened with water, and it should be used in the press in a cold state, and not heated, as is frequently the case in ordinary lithographic printing.

I have not detailed the optical arrangements for primarily obtaining the pictures or images, as such arrangements do not form any part of my said invention.

Having thus fully described and ascertained the nature of my said invention, and also the manner in which it is to be performed, I would observe in conclusion that what I consider novel and original, and therefore claim as constituting my said invention, are:—

Firstly, the production of photographic pictures or images by means of the sensitized ink or composition hereinbefore mentioned, or any sensitized ink or composition analogous or equivalent hereto, in the manner hereinbefore substantially set forth and described.

Secondly, the methods of transferring the photographic pictures or images so produced as aforesaid to the surfaces of such substances as hereinbefore particularly mentioned, and of printing from such surfaces as are adapted for such operation, as hereinbefore substantially set forth and described.

And thirdly, the methods of preparing the several materials employed in the process aforesaid, as and for the purposes hereinbefore set forth and described.

DOINGS OF THE SUNBEAM.*

We have copied a picture, but we can take a portrait from Nature just as easily, except for a little more trouble in adjusting the position and managing the light. So easy is it to reproduce the faces that we love to look upon; so simple is that marvellous work by which we preserve the first smile of infancy and the last look of age: the most precious gift Art ever bestowed upon love and friendship!

It will be observed that the glass plate, covered with its film of collodion, was removed directly from the nitrate of silver bath to the camera, so as to be exposed to its image while still wet. It is obvious that this process is one that can hardly be performed conveniently at a distance from the artist's place of work. Solutions of nitrate of silver are not carried about and decanted into baths and back again into bottles without tracking their path on persons and things. The *photophobia* of the "sensitized" plate, of course, requires a dark apartment of some kind: commonly a folding tent is made to answer the purpose in photographic excursions. It becomes, therefore, a serious matter to transport all that is required to make a negative according to the method described. It has consequently been a great desideratum to find some way of preparing a sensitive plate which could be dried and laid away, retaining its sensitive quality for days or weeks, until wanted. The artist would then have to take with him nothing but his camera and his dry sensitive plates. After exposing these in the camera, they would be kept in dark boxes until he was ready to develop them at leisure on returning to his *atelier*.

Many "dry methods" have been contrived, of which the *tannin process* is in most favour. The plate, after being "sensitized" and washed, is plunged in a bath containing ten grains of tannin in an ounce of water. It is then dried, and may be kept for a long time without losing its sensitive quality. It is placed dry in the camera, and developed by wetting it and then pouring over it a mixture of pyrogallic acid and the solution of nitrate of silver. Amateurs find this the best way for taking scenery, and produce admirable pictures by it, as we shall mention by-and-by.

In our former articles we have spoken principally of stereoscopic pictures. These are still our chief favourites for scenery, for architectural objects, for almost everything but portraits,—and even these last acquire a reality in the stereoscope which they can get in no other way. In this third photographic excursion we must only touch briefly upon the stereograph. Yet we have something to add to what we said before on this topic.

One of the most interesting accessions to our collection is a

series of twelve views on glass, of scenes and objects in California, sent us with unprovoked liberality by the artist, Mr. Watkins. As specimens of art they are admirable, and some of the subjects are among the most interesting to be found in the whole realm of Nature. Thus, the great tree, the "Grizzly Giant," of Mariposa, is shown in two admirable views; the mighty precipice of El Capitan, more than three thousand feet in precipitous height,—the three conical hill-tops of Yo Semite, taken, not as they soar into the atmosphere, but as they are reflected in the calm waters below,—these, and others, are shown, clear, yet soft, vigorous in the foreground, delicately distinct in the distance, in a perfection of art which compares with the finest European work.

The "London Stereoscopic Company" has produced some very beautiful paper stereographs, very dear, but worth their cost, of the Great Exhibition. There is one view, which we are fortunate enough to possess, that is a marvel of living detail,—one of the series showing the opening ceremonies. The picture gives principally the musicians. By careful counting, we find there are *six hundred faces to the square inch* in the more crowded portion of the scene which the view embraces,—a part occupied by the female singers. These singers are all clad in white, and packed with great compression of erinoline,—if that, indeed, were worn on the occasion. Mere points as their faces seem to the naked eye, the stereoscope, and, still more, a strong magnifier, shows them with their mouths all open as they join in the chorus, and with such distinctness that some of them might readily be recognized by those familiar with their aspect. This, it is to be remembered, is not a reduced stereograph for the microscope, but a common one, taken as we see them taken constantly.

We find in the same series several very good views of Gibson's famous coloured "Venus," a lady with a pleasant face and a very pretty pair of shoulders. But the grand "Cleopatra" of our countryman, Mr. Story, of which we have heard so much, was not to be had—why not, we cannot say, for a stereograph of it would have had an immense success in America, and, doubtless, everywhere.

The London Stereoscopic Company has also furnished us with views of Paris, many of them instantaneous, far in advance of the earlier ones of Parisian origin. Our darling little church of St. Etienne du Mont, for instance, with its staircase and screen of stone embroidery, its carved oaken pulpit borne on the back of a carved oaken Samson, its old monuments, its stained windows, is brought back to us in all its minute detail as we remember it in many a visit made on our way back from the morning's work at La Pitie to the late breakfast at the Café Procope. Some of the instantaneous views are of great perfection, and carry us fairly upon the Boulevards as Mr. Anthony transports us to Broadway. With the exception of this series, we have found very few new stereoscopic pictures in the market for the last year or two. This is not so much owing to the increased expense of importing foreign views as to the greater popularity of *card portraits*, which, as everybody knows, have become the social currency, the sentimental "greenbacks" of civilization, within a very recent period.

We, who have exhausted our terms of admiration in describing the stereoscopic picture, will not quarrel with the common taste which prefers card-portrait. The last is the cheapest, the most portable, requires no machine to look at it with, can be seen by several persons at the same time—in short, has all the popular elements. Many care little for the wonders of the world brought before their eyes by the stereoscope; all love to see the faces of their friends. Jonathan does not think a great deal of the Venus of Milo, but falls into raptures over a card-portrait of his Jerusha. So far from finding fault with him, we rejoice rather that his affections, and those of average mortality, are better developed than their taste; and lost, as we sometimes are, in contemplation of the shadowy masks of ugliness which hang in the frames of the photographers, as the skins of beasts are stretched upon tanners' fenees, we still feel grateful, when we remember the days of itinerant portrait-painters, that the indignities of Nature are no longer intensified by the outrages of Art.

The sitters who through the photographer's establishment are a curious study. They are of all ages, from the babe in arms to the old wrinkled patriarch and dames whose smiles have as many furrows as an ancient elm has rings that count its summers. The sun is a Rembrandt in his way, and loves to track all the lines in these old splintered faces. A photograph of one of them is like one of these fossilized sea-beaches where the

* Continued from page 356

rain-drops have left their marks, and the shell-fish the grooves in which they crawled, and the wading-birds the divergent lines of their foot-prints,—tears, cares, griefs, once vanishing as impressions from the sand, now fixed as the vestiges in the sand-stone.

Attitudes, dresses, features, hands, feet, betray the social grade of the candidates for portraiture. The picture tells no lie about them. There is no use in their putting on airs; the make-believe gentleman and lady cannot look like the genuine article. Mediocrity shows itself for what it is worth, no matter what temporary name it may have acquired. Ill-temper cannot hide itself under the simper of assumed amiability. The querulousness of incompetent complaining natures confesses itself almost as much as in the tones of the voice. The anxiety which strives to smooth its forehead cannot get rid of the tell-tale furrow. The weakness which belongs to the infirm of purpose and vacuous of thought is hardly to be disguised, even though the moustache is allowed to hide the *centre of expression*.

All parts of a face, doubtless, have their fixed relations to each other and to the character of the person to whom the face belongs. But there is one feature, and especially one part of that feature, which, more than any other facial sign, reveals the nature of the individual. The feature is *the mouth*, and the portion of it referred to is *the corner*. A circle of half an inch radius, having its centre at the junction of the two lips, will include the chief focus of expression.

This will be easily understood, if we reflect that here is the point where more muscles of expression converge than at any other. From above comes the elevator of the angle of the mouth; from the region of the cheek-bone slant downwards the two *zygomatics*, which carry the angle outwards and upwards; from behind comes the *buccinator*, or trumpeter's muscle, which simply widens the mouth by drawing the corners straight outward; from below, the depressor of the angle; not to add a seventh, sometimes well marked,—the "laughing muscle" of Santorini. Within the narrow circle where these muscles meet the ring of muscular fibres surrounding the month the battles of the soul record their varying fortunes and results. This is the "*nœud vital*"—to borrow Flouren's expression with reference to a nervous centre,—the *vital knot* of expression. Here we may read the victories and defeats, the force, the weakness, the hardness, the sweetness of a character. Here is the nest of that feeble fowl, self-consciousness, whose brood strays at large over all the features.

If you wish to see the very look your friend wore when his portrait was taken, let not the finishing artist's pencil intrude within the circle of the vital knot of expression.

(To be continued.)

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, 29th July, 1863.

MR. HART, of London, at the recent meeting of our Society, exhibited a positive printing frame, in which, by introducing a dissected screen, a positive proof can be taken from different negatives. The principal object kept in view in constructing this apparatus is the facilitating the adjustment of the negatives and screens employed in taking positives from several negatives. The small model exhibited has been made to obtain proofs upon tinted grounds, intended to be retouched, an operation that succeeds very well with proofs of small dimensions.

The following is the principle of construction:—Take a piece of very dry wood, of such size that it exceeds the dimensions of the largest proofs to be taken by 2½ to 3 inches on each side. Upon the middle of this board is placed a thick sheet of caoutchouc, selected for its eminently elastic qualities; this sheet must be a little larger than the proof to be printed in the frame. At the extremity of this sheet a rod of the same thickness is placed, which, pressing against it by means of a spring, maintains the positive paper in a fixed position. Over the whole a hinged frame is adjusted, made to move horizontally in every direction,

and so arranged that while the hinged extremity is fixed, the greater portion of the frame may be raised to permit the examination of the progress of the picture, without fear of displacing the negative, or the screen which covers a portion of the positive. This frame must be solid; it carries either one or two bars, for the purpose of keeping the glass plate or negative in the desired position in relation to the prepared surface. When the printing necessitates the employment of many negatives, it is preferable, in the inventor's opinion, to transfer the latter to gelatine or other transparent support, and to adjust them on the plate as they are adjusted in the frame, nearly in the desired position, and to arrange them afterwards in a manner conformably to the portions already printed.

M. François Pierson has invented a machine for beating albumen, which he has for a long time employed in preparing paper. The metal dasher with which the eggs are beaten, is moved mechanically with great rapidity, by means of a fly-wheel, which turns freely, and a system of eccentrics. The vessel containing the albumen turns upon itself continually during the operation. By means of this machine we can beat into froth, in the space of five minutes, as many eggs as forty minutes' fatiguing labour would not suffice to bring to the same condition.

M. Hulot exhibited to the society his method of splitting and parchmentizing paper. The paper is immersed in sulphuric acid diluted with 20 per cent. of water, and allowed to remain a given time, according to the nature and thickness of the paper which is afterwards rinsed in water. Thus treated, the paper splits with great facility, and the sulphuric acid having closed the pores, it has much more compactness, gaining in consistency while becoming thinner. It is remarkable that the colour does not change. This treatment may be applied to negative proofs only, as M. Adolphe Martin observes that this paper, after being parchmentized, cannot be waxed.

M. Lucy has communicated his method of the chemical colouration of proofs in the toning bath. The tints, which produce a remarkable effect in the flesh and drapery, are produced by a combination with the chloride, which enters into the preparation of the paper with a metallic chloride, which the operator applies, before immersion in the toning bath, to those parts of the picture he wishes to colour. The reaction then takes place, and the hue is according to the salt employed. The alkaline chlorides are the best.

Dr. Schnauss has published in the *Photographisches Archiv*, an analysis of the metallic bromo-iodo-cyanide salt, to prepare and sensitize the instantaneous collodion composed by M. Mazac. This preparation contains *iodine, bromine*, and the metals *ammonium* and *cadmium*, but no cyanide. To prepare a collodion identical with that of M. Mazac's, Dr. Schnauss gives the following formula:—

Iodide of ammonium	4 parts.
Iodide of cadmium	2 "
Bromide of cadmium	1 "

The sulphate of iron and ammonium has become, in Germany, the source of a very censurable industry. We read in the principal newspapers advertisements inviting photographers to send ten dollars, for which they will receive the formula of a new developer for very vigorous and delicate negatives without intensifying. One of these advertisers impudently asserts that "he is honored with a medal from the Great Exhibition." Upon opening the letter containing this precious formula, we find sulphate of iron and ammonium recommended. A photographer addresses the following letter to us on this subject: "X is a cheat; for the ten dollars he sends the following formula:—

Iodide of potassium	...	150 grains.
Bromide of cadmium	...	65 "
Iodide of cadmium	...	85 "
Collodion, composed of equal parts of ether and alcohol	...	31 ounces.

Develop with the solution of sulphate of iron and ammonium, according to M. Liesegang's formula."

With regard to the solution for strengthening collodion negatives, recommended by M. Valentine Blanchard, in the PHOTOGRAPHIC NEWS, M. Liesegang remarks that the solution improves by keeping. It is employed in exactly the same manner as pyrogallie acid, adding to it a quantity of the nitrate of silver solution, and pouring the mixture upon the developed proof; its action is prevented until the negative has become sufficiently vigorous. The advantages of strengthening by means of iron compared with pyrogallie acid are, that the precipitate of silver is finer, that the solution keeps better, and never fogs the shadows. The solution may be employed before or after fixing. It would appear that this new method will be very advantageous for instantaneous negatives, which are frequently very feeble.

Tartaric acid, as recommended recently by yourself may be advantageously substituted for citric acid, and, when mixed with nitrate of silver, remains clear until the necessary intensity is obtained.

Some operators recommend the saccharo-sulphate as giving much intensity to the proof.

Our Paris Photographic Society is undergoing the same kind of transformation which photography itself has undergone, by acquiring a wholly scientific character. What makes a society is less the aim with which it is established, than the influence of the members composing it. Now the Society's bulletin, of the 15th of May last, contains a list of its members, which, it must be recognised with pleasure, belong, for the most part, to the most intelligent and enlightened classes of society, both native and foreign. What is particularly remarkable, is the esteem and the *great authority* which attaches to some members whose scientific and practical works have made their names popular. As has been well remarked, this must have a considerable influence upon the future of the Society, and on the value of its labours. But a few years ago the French Photographic Society was surrounded with hostility; at Paris, especially, it was feared that the spirit of clique would prevail, and it was seriously apprehended that the Society had no future. Its works could not be placed in comparison not only with those of the Photographic Society of London, but also with many provincial societies in the United Kingdom. At the present day, every impartial person must admit that this Society, far from realizing the doubts prevalent at its *début*, has, on the contrary, fully accomplished the mission it proposed to itself, as much by the foundation of prizes intended to stimulate works upon subjects which interest photographers, as by the authority it gives to a portion of its members most eminent by their intellectual acquirements. Its *Bulletin* has become an indispensable journal to every one engaged in photography, and we recognise with pleasure that its selections from foreign journals are well made, and without the least party spirit.

We have only one objection to make to the French Photographic Society: its subscription is too high. We do not believe that we are singular in our view, for we have often heard it expressed, and we repeat the opinion of high authority when we say this. The amount of subscription should not be much more than the subscription to the *Bulletin*, for abroad the title of member of the Society brings no other advantage than the monthly receipt of the *Bulletin*. Now, to make members pay triple that amount is not good policy, and if the amount were reduced to one-half, in a very few years the number of its members would be increased tenfold.

M. M. Davanne and Girard, as is well known, have pointed out an excellent means of preserving the sensitiveness of positive paper, and preventing it from turning black—by preserving it in a box containing chloride of calcium, or other desiccating substance. It may be well for those who employ these boxes to know that the paper should first be exposed to the air in a dark place in order to acquire a certain amount of humidity, without which it will darken but very slowly in the pressure frame.

We can obtain great intensity in developing collodion plates by moistening them after cleaning, and covering them with albumen diluted with its volume of water. The dried plates are covered with collodion, and developed in the usual manner. For studies of trees and landscapes generally, pyrogallie acid is preferable to sulphate of iron.

DOES LIGHT ONLY EXIST IN THE EYE?

DEAR SIR,—There are one or two statements in the interesting paper on light, under the head "Scientific Gossip," in your last number, to which, I think, exception may be taken without incurring the charge of hyper-criticism.

The writer comes to the conclusion that the blue sky is yellow, sunshine red, &c. This may be the case if the eye were in those regions to see their colours, though they would not necessarily assume the tints fixed upon by your correspondent. I notice this assertion, not to question it, but to remark that it is at variance with what follows, viz., "All this universe is dark." If it be correct to say the sky is blue or yellow, it is incorrect to assert that it is dark. Light and darkness are both sensations (unless darkness be called the sensible absence of the sensation of light), and it requires the presence of the eye to decide how far either exist, and that place only can properly be termed dark in which an eye fails to perceive light. It is true that in one sense there may be said to be no light where there is no eye to behold it—that is, in every place external to the eye; but it is equally correct to say that in such places there is no darkness, both light and darkness being attributes of the optic sense, and not existing independent of it. It was, no doubt, the meaning of the writer, that in the universe there was no light independent of the eye, but it does not follow that the universe is dark, and such an expression is incorrect. Equally so is it to say, "Light exists only in the eye." Light is not in the eye, or in the optic nerves, but in the optic sense or sensorium, whatever or wherever that may be. The eye is merely the material instrument, perhaps the first in a series of many, by means of which what are called waves of light are prepared for their mysterious action on the sense of sight, and is as much a medium as the atmosphere through which the ethereal vibrations are propagated. Your correspondent will perceive that I do not criticise his statements, but the form in which he has put them; but when the usually received meaning of words is departed from, and they are used in an exact philosophical or metaphysical sense, the greatest care is requisite to preserve consistency in their significations, lest confusion of ideas should be introduced into the minds of those to whom it is endeavoured to convey abstruse knowledge.—Yours truly,

M. A.

SUCCESSFUL LIME TONING.

SIR,—I was a most unfortunate man, but thanks to you, am, I hope, one no longer. Unlike "Cha-meal-ion," I have not hitherto been fortunate in getting the tone I required, *i. e.*, black and white. It was, therefore, with great pleasure I read in your number of the 17th Mr. Parkinson's method of obtaining them. I instantly prepared a bath according to your directions, and having only the Saturday afternoon, at present, to experiment in, I have been through the week looking forward to that day with no small anxiety. You can imagine my dismay, then, at reading "Cha-meal-ion's" letter, for I had mixed my bath exactly as he described his. However, as I had some prints prepared on purpose, I thought I would try for myself, when, judge my surprise and joy at finding them gradually attain the long-desired rich warm black. I can, therefore, only fancy that my materials were better.

Perhaps it would be better to describe accurately the way in which I proceeded:—

I obtained from Messrs. Hopkins and Williams a saturated solution of chloride of lime, into which I put some car-

bonate of lime, shook well, and *let it stand for several days*. The paper was the *thin paper* of Messrs. Murray and Heath. Into 35 ozs. of distilled water I filtered $1\frac{1}{2}$ drachms of the lime solution, and then added 2 drachms of gold. This I used twenty-four hours after mixing. I cannot tell the strength of my silver bath, as it was one I have had in use some time. The prints were a little over-printed, then well washed, put into the toning bath out at a time, with only just sufficient to cover them, and the result was most satisfactory, and has put an end to all my troubles on this head. My time is so fully occupied professionally at present, or I would send you some proofs to look at, but as soon as I am a little more disengaged I will do so, that you may see I do not over-rate my success.—I am, dear sir, yours truly,

July 27th, 1863.

ENGINEER.

Photographic Notes and Queries.

ANGLE OF VIEW, &c.

SIR,—In the last number of the PHOTOGRAPHIC NEWS, your correspondent, "Tanno-Glycerine," asks your advice as to the form of lens best adapted for general purposes, and also for engineering subjects, bridges, &c., where a large angle of view is required, say 60° or 65°, the size of picture wanted being 11 by 9. You tell him in reply that you do not know of any lens at present catalogued which will give an angle of 60° or 65° on 11 by 9 plates.

Permit me to call your attention to the following extract from the PHOTOGRAPHIC NEWS, for March 29, 1863, page 261:—

"Mr. Collis exhibited a series of fine views in Wales, taken with Ross's 10 × 8 triple lens, on 10 × 12 plates. Also some with the lens of 8·4 focus, and some with the lens of 9·4 focus, including an angle of 60° on the base line and 66° on the diagonal. These were very much admired."

My triple lens of 9·4 equivalent focus is therefore the very lens which would answer the requirements of your correspondent, but I suppose you had for the moment forgotten that such a lens is in existence.

In fairness to yourself, to your correspondent, and to me, I must request the favour of this letter being inserted in the next number of the PHOTOGRAPHIC NEWS.—Faithfully yours,
THOMAS ROSS.

2, Featherstone Buildings, Holborn,
July 28, 1863.

[Neither the lens nor the prints referred to came under our especial attention for measurement or calculation; their exhibition at a meeting, and our incidental sight of them, were duly reported at the time, but had escaped our further recollection.—Ed.]

EBONITE BATHS.

DEAR SIR,—Having long been a subscriber to your NEWS, I take the liberty of addressing you regarding a subject which may prove beneficial to others.

Seeing ebonite so highly spoken of for baths, I immediately sent home to one of the best houses for a bath. I have had it now in use for two months and more, and have always found that after my bath had been in for a couple of days I could never take a good picture. I saw it had all the appearances of acidity, but could not make out how it had got acid. This morning being a particularly nice morning, I thought I would take some pictures. I exposed, and did everything as usual, but no negative. I immediately went to my bath and found that the acid state was enough to prevent any picture. I after emptied it out into the stock bottle, and applied a piece of litmus paper to the ebonite, it immediately turned it scarlet: I may say, this ought not to be, I should think. To prove there was nothing wrong with the bath itself, I put a little in a small glass bath I had, and instantly took everything as usual. Is this the usual behaviour of this patent material? because, if so, the sooner it is generally known the better. I put in boiling soda and water to see what effect it would have, but have not had time to try; but shall be happy to let you know, if you think it worth

knowing. Perhaps some of your numerous readers can enlighten me on this subject.—I am, dear Sir, yours faithfully,

DENNIS WRIGHT, Captain 109th Foot.

Kurrachee, Said, June 9, 1863.

June 20.—I have since tried the bath, and find it is not the slightest better now than before.

[We cannot see any possible action in ebonite which could render the bath acid; nor, if it had done so, could the same solution have worked properly at once, without any rectification, when placed in another vessel. We have had a silver solution standing in an ebonite bath for upwards of twelve months, without being in any way injured.—Ed.]

Talk in the Studio.

RESINIZED COLLODION.—Dr. Saunders Van Loo, writing to us from Amsterdam, says:—"It is more than two years that I have used this collodion, and always with the same success. Since that time, no great improvements have been made in dry plate photography, except ammonia fuming, hot developments, &c. I am sure no simpler method exists than to prepare with my resinized collodion, plates which are simply washed in ordinary water. The chlorides present in the wash water do not give any trouble. I use always the here called "duinvater," or hill water, which is conducted from a distance of four hours to Amsterdam through iron tubes. This water contains lime and iron salts. My plates keep fit for use for a long time; I have exposed and developed with success plates which were prepared for several months. Therefore it surprises me that resin-collodion is not more in use. Sometimes I read in your valuable journal about trials by some gentleman to get dry collodion by adding resin to Ponting's, Thomas', or other good collodion sorts, yet I suppose that a photographer will scarcely succeed in this way for obtaining a suitable dry collodion. Enclosed I have the honour to send you a print after a negative taken in *two minutes, with stopped view lens* (opening scarcely half an inch). I expect that the correspondence in photographic journals would not abound in so many narratives about disappointments in dry-plate work, if resin-collodion in good condition was more used.

[Some time last year, Dr. Van Loo favoured us with a bottle of his collodion for trial. Unfortunately, press of engagements delayed our trial for some months, and we then found that the collodion had lost sensitiveness by age, so that we were unable to do it justice in a trial.—Ed.]

THE DISCOVERY OF THALLIUM.—Mr. Crookes has just issued a pamphlet detailing the history of his discovery of thallium. With singular disingenuousness the French *savans* persist in attributing the discovery of the metallic nature of this element to M. Lamy, and state that Mr. Crookes is indebted to that gentleman for his knowledge that thallium was a metal. We have before alluded to the evidence on the subject, which is most conclusive, and it is unnecessary to repeat it now. M. Lamy states that he first discovered the green line of thallium in April, 1862, and that he isolated the metal in May, 1862, between the 2nd and 16th. Now the fact stands on uncontested published evidence that Mr. Crookes discovered the line in March, 1861, isolated the element in September, 1861, and exhibited the metal on the 1st of May, 1862, at the opening of the International Exhibition, upwards of a fortnight before M. Lamy announced his discovery of the metal.

MR. HEATH'S PHOTOGRAPHS.—Mr. Vernon Heath issued circulars a few days ago, inviting his friends to a private view to a series of portraits and landscapes recently taken for His Royal Highness the Prince of Wales. The views of Windsor and Frogmore include some of the most charming photographs that we have seen. Amongst the many pleasing portraits of the Prince and Princess, we were most interested in the enlargements from card pictures to whole plates, which were produced with scarcely the least appreciable loss of any kind, either in definition, delicacy, gradation, or vigour. Mr. Heath, after very long experiment in the enlargement of negatives, has come to the conclusion that the most perfect result is obtained by obtaining first a good, well-detailed transparency, using iron development, and, from this, a negative, by weak pyrogallic acid development. The perfectness of the results very emphatically recommend the method.

ART PHOTOGRAPHS.—We have received from Mr. Adam Diston, of Leven, Fife, three subject pictures produced by the camera, which display very considerable artistic power. The

best is intended to represent Alexander Selkirk's first day on the island of Juan Fernandez, illustrating the passage, "Thus he remained seated on his chest until darkness shut out every object from his sight." A sailor is seated on a sea-chest on the shingly shore, his head resting on his hand; his gaze is fixed across the sea, scanning the wide expanse with intense and eager look to desery anything which may give him hope. The picture is simple, and natural, and effective. Another picture presents a cottage interior, where a mother knits a coarse stocking and rocks a cradle with her foot at the same time. The third might be termed a new version of the *Belle Jardiniere*, except that the model, although a healthy rustic wench, is scarcely beautiful. The pictures are about 10 by 8, vignettted, and the photography very excellent.

REDUCING RESIDUES.—A correspondent says: "For the benefit of any who, like myself, have been unable to get sufficient heat to reduce the ashes from paper, &c., I may suggest that if they have an iron foundry near they may save themselves much unnecessary trouble by taking it there. I had 12 ounces of ashes, which was put in a clean crucible for melting brass, in what they termed the brass stove, from which I got 6½ ounces of metallic silver."

ANGLE OF VIEW.—We have received from "Tanno Glycerine," whose letter appeared in our last, a couple of prints referred to in the letter. They are both on 11 by 9 plates, but one is by Dallmeyer's triple No. 1, 8 inches equivalent focus, and the other by a caloscopic lens of 11½ inches focus. The amount of angle included by the former is enormously larger than by the latter, and the definition to the edges about the same; having been taken by waxed paper process, it is difficult to speak with the same certainty on the quality of the definition as if the negatives had been on collodion plates. It is somewhat singular that our correspondent, aided by a scientific friend, Mr. William Salkeld, C.E., had been trying, before seeing our note to his letter, the very method of measuring the angle we suggested, namely, the use of a protractor to measure the angle formed by the base line of the picture and the equivalent focus of the lens. They had ascertained the angle by calculation, and by taking a view and measuring the subject with a theodolite, each method confirming the other. We shall shortly have some further remarks on the subject.

To Correspondents.

W. D. B.—Excited albumenized paper may be used to test the non-actinic colour of glass, but unless it withstand the action of light entirely during very prolonged exposure, there is not much certainty obtained as to its suitability for the dark-room, as the difference between the sensibility of excited paper and a sensitive collodion film is almost incalculable. We generally use the spectroscope, which is a certain method of testing; but you may obtain certainty for yourself, if you desire, by placing the glass in contact with an excited collodion film and exposing it for a minute to the light, and then developing. If the film show no deposit whatever where it was protected by the glass, you may glaze your room with the same used without fear.

THOMAS JONES.—All the residues from your sink, cyanide, hypo, &c., may be treated with sulphide of potassium, and the silver recovered as a sulphide.

AN OLD PHOTOGRAPHER.—We believe that Mr. Solomon sells an apparatus for taking microscopic photographs.

M. A.—So far as we can speak with certainty, a good rule with ordinary tannin plates is to give them 6 or 8 times as long exposure as would be given to wet plates under the same circumstances. We do not know much of the constitution of Mawson's collodion, but we believe it to be slightly ironized. For the tannin process you would probably be safe in adding to it bromide of cadmium at the rate of a grain to the ounce. 2. The appearance of the image on a tannin plate after exposure and before development is often the result of over-exposure, but it is not necessarily the case; some qualities of collodion have a tendency to give it.

WAXY sympathies deeply with our correspondent "Cha-meal-ion's" troubles in connection with the lime toning bath. He says that his own "warm flesh tints" are disappearing, and that he is becoming pale and haggard; that he has absolutely discovered three grey hairs in his "rich black" locks; that he is, in short, becoming mealy himself, in trying to use the lime bath successfully. He wishes to know where Mr. Parkinson's paper, gold, and lime were obtained. So far as we know, the first was obtained from a provincial French town, the second from Paris, and the third from the nearest oil-shop to his atelier in Dieppe. See communications from Mr. Hughes and "Engineer," in the present number. We have within the last few days ourselves tried Parkinson's toning bath with perfect success. We shall probably have something to say on the subject in our next. The chloride of lime is such as we procure from the oil-shop. There is no need of any special preparation.

S. S. STARBUCK sends us a very good card picture as a specimen of his work as a negative operator of four months' experience. It is highly creditable to his skill and industry. The only improvement it needs is a trifle longer exposure of the negative.

J. E. WHITEHEAD.—The embossed paper referred to was simply an experimental sample prepared for Mr. Cooper, after the method described in our pages a few weeks before the allusion to which you refer. It has not been

prepared for sale as yet. We have not heard whether Mr. Cooper has made any progress with his experiments in that direction. Our correspondents must excuse us writing private letters on subjects which can be answered here. Our time would be more than fully occupied with letter-writing if we did so, and it is already considerably over-taxed.

PHOTO.—Nothing could be worse than the system you are advised to adopt. If you give the prints only two changes of water after coming from the hypo, and then leave them soaking all night, you leave them for hours in what is practically a weak hypo bath, than which nothing can be more destructive to the brilliancy and purity of the print, and possibly to its permanency. Washing for a couple of hours in six or eight changes of water, rapidly given at first, would be much more efficacious than such a system.

HICSON AND POOLE.—A saturated solution is easily made by taking care to have excess. The exact amount of either chloride of lime or carbonate soluble in water varies under different circumstances. The latter is scarcely soluble in pure water at all, but it is soluble when any carbonic acid is present, which in most waters it is in greater or less degree. We regret our inability to answer in private letters questions of this kind. Letters containing such questions are rarely even read until the appointed time for answering all in this column at one time.

CHURK.—Your best plan is to begin by neutralizing your bath with carbonate of soda, then sun for a few hours. Boiled rain water will, probably, contain some traces of organic matter, and sunning will precipitate it. Bear in mind, however, that the streaks to which you refer often arise with certain samples of collodion, and are entirely absent with another collodion in the same bath. 2. Nitric acid added to carbonate of soda will give nitrate of soda.

PETER GRIFFITHS.—The yellow stains are caused by some trace of hypo coming into contact with the prints before they are fixed, either from fingers or dishes. If the prints are washed in the same dishes, before fixing, which are used for washing them after fixing, traces of hypo sufficient to cause such stains will often hang about the dishes.

B. W. S.—The superficial fog you describe, which will brush off, and to which, if everything is not in perfectly good condition, there is often a tendency in hot weather, may often be prevented by decreasing the strength of the developer and using more acid in it. If this be insufficient the bath is at fault, and you had better neutralize and sun it. 2. The white stain you describe, probably arises from the drainings of the plate coming in contact with some foreign matter at the corners on which the plate rests.

C. E.—Rain water which has become brown from contact with organic matter may be rendered quite pure and suitable for washing dry plates by the addition of Condry's fluid. Chlorides will not be removed, however, from hard water by the same application. Distillation is the proper method of removing chlorides.

M. P.—Your negatives generally have been insufficiently exposed, and want a little more care to secure sharpness. No. 1 is much under-exposed, and altogether too thin to give good results. No. 2 is not sharp and is under-exposed. The varnish chilling is caused by using a spirit varnish without heat. The portions of the paper which you have marked with a cross have not come into contact with the silver solution, and the albumen has consequently been washed off in the subsequent operations. The brown stain in the middle of the print is from a defect in the paper caused by an irregular flow of the albumen. No. 3 is much under-exposed and a little fogged. No. 4 is the best; the streaks are apparently caused by an imperfect and uneven layer of collodion, possibly from the fault of the collodion, possibly from bad manipulation. Be more careful to get a perfect, even film without ridges or lines, and do not immerse the plate so quickly after coating. 2. You will find an article on collodion in our ALMANAC. 3. Always use glacial acetic acid, which is a definite article; its strength is indicated by its crystallizing at a temperature of 50° Fah. Beaufoy's acetic acid is an article of uncertain strength, generally containing about one third of real acid. The term "acetic acid No. 8" is a phrase used in America, and relates to the classification used there. 4. Some toning solutions may be used over and over—the acetate bath for instance. 5. A strong, hot solution of soda will cleanse a greasy bottle; rinse it well afterwards, before putting chemicals into it. 6. You may intensify after the plate is dry. Read the article on intensifying in our ALMANAC. 7. Plain collodion is uniodized. Pyroxylene is cotton which has been submitted to the action of acids, and rendered soluble for making collodion.

L. S. B.—In order to copy a picture the same size as the original, it must be placed at a distance from the lens equal to double the equivalent focus, and the camera must be extended to the same length. For instance, with your No. 1 B, which has an equivalent focus of between 5 and 6 inches, fix up the picture to be copied, and place the camera so that the lens is about 11 inches from the picture, and draw out the camera so that the ground glass is 10 or 11 inches from the lens. This done, a very little adjustment will give you a sharp image the size of the original. Use a small stop, and give sufficient exposure.

G. B. D.—The Photographic Exhibition in Paris is in a part of the Palais de l'Industrie, in the Champs Elysees. Several correspondents in our next.

THE LIME TONING BATH.

Nothing is more perplexing than the occasional discrepancies in evidence as to the specific results of some given formula. A adopts a certain toning process, and by patient experiment and watchful care he obtains perfect success. He finds great advantage from certain minor modifications, and after having, as he believes, obtained great certainty as to the most successful proportions and manipulations, he publishes for the benefit of his brethren in the art the results of his experience. B, who has been anxiously aiming at the tones described, at once tries the process; but he gets no better results than he did with the various baths he had tried before; some of the prints are pretty good; but the majority are flat, feeble and brown, or grey and mealy. The fact is, his negatives are thin and veiled, and can never yield such prints by any process; but he does not take this into account in his failures: indeed, he is probably scarcely conscious of it. C also tries the process, he has succeeded well hitherto, but is always anxious to improve. To his disgust every print is bleached, mealy and useless. He has followed the formula accurately; but his paper, his gold, his mode of printing are altogether different from those of A, and his results are also different, with a vengeance. D also tries the method. He is never much in the habit of weighing, he can measure pretty well with his eye; some of his conditions he knows are slightly different, but that is a thing too trivial to affect the matter much, he says. He fails entirely, and at once declares his conviction that A never succeeded with the process as he described it; but that some little important secret is held back. "They never do tell all they know, these fellows who profess to be so liberal!" he exclaims, and is satisfied that the process was described either entirely falsely, or with a reservation. Perhaps E, F, G, and the rest of the alphabet, succeed perfectly; some of them say so; but the majority are not much in the habit of talking, and still less of writing, and when they hear of the failures of the others they simply shrug their shoulders and say, "Oh, they never succeed in anything!"

We have recently called the attention of our readers afresh to the special characteristics of the toning bath of gold and lime, not as necessarily recommending it for all purposes, as, everything considered, we prefer the acetate bath for general use, but as giving certain qualities which many professional photographers are desirous of obtaining. We have published several formulæ, which we had either tried ourselves, or the results of which we had seen. We have had, since we published these formulæ, many communications on the subject, stating singularly discrepant results. There have been many failures, of which those detailed in the humorously pathetic letter of "Chameal-ion," which we recently published, may be taken as a sample. At the time we described Mr. Parkinson's formula

we had not tried it, but we had seen some hundreds of prints with a uniformity of rich black tones which we had not seen equalled before.

We have within the last week or two tried the formula several times, just as we stated it, and with the most satisfactory results. We first tried it in an hour after mixing. The result was, that on one sample of paper we obtained good prints with a trace of meanness, but on another sample from the same maker, the tone and quality were in all respects good. When the solution had been mixed six hours, we tried it on another sample of paper which had been sensitized and printed by a friend, who had brought the unfixed print to show us the quality of a certain negative. The paper was old and discoloured, but the toned print was perfect in tone and purity. In all the prints toned on the first day there was a little bleaching action, but trying it again, when four days old, we were surprised to meet with an action rarely secured in the toning bath; it very considerably increased the amount of contrast in the print, by toning the shadows a deep black, without in any appreciable degree bleaching them, or reducing their depth; and the sample of paper giving some degree of meanness the first day was now totally free from it. The chloride of gold was an ordinary sample, we believe, of French manufacture, very slightly acid. The chloride of lime had been kept in a well stoppered bottle for two or three months. We tried several samples of paper, which had been sent to us for trial at different times—they consisted of Lampray's enamelled paper, and his Sutton's patent paper; of Elliott's albumenized paper; of Hart's albumenized paper; and one or two others we don't remember.

What, then, are the special advantages of the lime toning bath, and what are the causes of the difficulties which occur in its use? Its advantages are chiefly to the portraitist who desires a pure black tone. Such a colour is rarely desirable for landscapes, and not always for portraiture. But the lime bath possesses this especial characteristic: when the deep shadows of the print toned in it are black the half-tones are of a warm neutral tint. With some toning baths it is difficult to get a black at all, if the print be pushed beyond a deep purple it becomes a greyish blue. With others, when the black tone is attained, the most delicate half-tones surrounding the high lights are gone altogether, and the remainder are grey and cold. The advantages of the lime bath are that it gives a very deep rich black to the shadows and a warm tint to the half-tones. The difficulties arise partly from the fact as explained by Mr. Hughes in our last, that it is very sensitive to the slightest change of conditions, and partly from the fact that the chloride of lime is a most inconstant and uncertain compound.

Chloride of lime is a somewhat unscientific name for a somewhat indefinite preparation. It is formed by passing chlorine gas through hydrate of lime. At first sight this would appear to be a simple mechanical mixture, the lime serving as a vehicle for carrying the chlorine; but an odour

is exhaled which is sensibly different from pure chlorine. The compound is generally regarded as consisting of hypochlorite of lime, chloride of calcium, free chlorine, and lime. Chloride of lime is said to be soluble in ten parts of water, which is equivalent to forty-eight grains to the ounce. It appears to be, however, more probably decomposed by water, as on adding this proportion to form a saturated solution a bulky precipitate is formed, which consists simply of hydrate of lime deprived of its chlorine. It will be seen from this that formulæ containing what is termed a saturated solution are apt to be misleading, as the manipulator is very apt to suppose he has obtained a saturated solution as soon as he sees a permanent precipitate, which will occur, however, long before he has obtained a really saturated solution. Again, chloride of lime is constantly changing in composition. In a vessel exposed in any degree to atmospheric action it is destroyed by the absorption of carbonic acid. Even when kept carefully stoppered a slow change is taking place, by which it is eventually converted into chlorate of lime and chloride of calcium.

If a really saturated solution of freshly made chloride of lime be made by dissolving about forty-eight grains in an ounce of water, a drachm will contain six grains; sufficient, and sometimes too much, for two or three grains of gold. Carbonate of lime is very sparingly soluble in ordinary water, which rarely dissolves more than half a grain to the ounce. In Parkinson's formula, it will be seen that if the chloride of lime have been freshly prepared, and great care have been used to secure a saturated solution nearly four grains would be used to each grain of gold. Such a proportion would probably, in many cases, especially when newly made, give excessive bleaching and mealiness. In many cases it is probable that the chloride of lime used is not freshly prepared, and possibly the solution is not really saturated, the presence of undissolved hydrate of lime misleading the manipulator in this respect. It is quite possible that the difference between an old and a new sample of chloride of lime, and the difference between real and apparent saturation may account for the varying experiences of some careful manipulators, and may account for success and failure. The remedy for failure in such a case is to adopt the suggestion of Mr. Hughes in our last: where bleaching and mealiness exist, decrease the amount of chloride of lime; when it is difficult to get a sufficiently black tone increase the amount. There is another point which may be worthy of notice, it is this:—Experimentalists, when trying a new bath, very naturally commence by immersing one or two prints. Now, if the quantity of solution be sufficient for many prints, and it contain free chlorine, it follows from the great affinity of that element for silver that the prints are at once attacked, all the free chlorine in the solution sufficient for a score of prints, it may be, is at liberty to act upon one or two, and considerable bleaching ensues, sometimes to the entire destruction of the print. Mr. Parkinson, in a recent letter, speaks of putting two hundred prints at once into a sufficient quantity of solution to tone them, and leaving them, with occasional turning over, for an hour, when the toning was completed. In trying this bath, then, it is probably desirable to use no more of the solution than is required for toning the prints immersed in it, so that there may not be the free chlorine of a larger quantity of solution to act upon a small number of prints.

Although the method of preparing the bath adopted by Mr. Parkinson is very convenient, and gives such excellent results in some hands, possibly more certainty may be obtained by weighing a definite proportion of chloride of lime than in using a saturated solution. A method we have repeatedly tried, and always with success, is to make a solution of chloride of gold one grain to the ounce, to this add excess of carbonate of lime, agitating well, and leaving the excess at the bottom of the bottle; to each ounce of this add from one to two grains of chloride of lime if freshly made, and from two to three grains if it have been kept some time. When required for use dilute the solution by the addition

of seven or eight ounces of water. This should be ready for use in a few hours, or keep for weeks.

We subjoin Herr Liesegang's modification of a similar formula, and his comments thereon, given some time ago in the *Photographisches Archiv*.

Take any chloride of gold in the market, dissolve it in rain water; then add to this solution common chalk in quantity of about one-sixth the weight of the chloride of gold dissolved; the chalk must be finely pulverized before it is mixed with the gold solution. The free acid of the gold combines with the lime and forms chloride of calcium, leaving probably a small quantity of carbonate of lime. After standing for an hour or two, shaking frequently in the meanwhile, the solution is filtered through broken glass and kept for use; it is a solution of the double chloride of gold and of calcium. If 15 grains of ordinary acid chloride of gold were used in the solution, then, to form the toning bath, take 45 ounces of rain water with which mix the solution of the double chloride; to this mixture add of a solution of chloride of lime until the whole assumes an alkaline reaction.

Of the value of the bath so made he speaks in the highest terms.

This description of gold bath, we are inclined to believe from experience, will last for a long time; at least, the qualities of a solution that has been prepared for more than a month have not undergone the slightest alteration; hence it may be argued that they will be retained much longer—a great advantage for amateurs, who only occasionally take a small quantity of the solution, dilute it with water, and thus can apply it.

This gold-toning bath for albumen paper is an important improvement. In the first place it is a clear and colourless solution, quite permanent, and immediately ready for use. Besides this, it does not bleach the prints, nor render them mealy like other gold baths. It is a solution of the double chloride of gold and of calcium, with a small addition of chloride of lime to neutralize the acid, and to give the solution a slightly alkaline reaction. The advantages of this solution over the gold bath, containing carbonate of soda, acetate of soda, and phosphate of soda, can easily be comprehended. All these baths are liable to change and precipitate the gold: the soda giving up the acid with which it is combined, enters into combination with the chlorine of the gold. But in our new bath the alkali is already in combination with chlorine, and thus neither withdraws chlorine from the gold salt nor precipitates the gold. When the excess of the alkaline salt is either a carbonate, acetate, or phosphate, the base gives up the weak acid with which it is in combination, and robs the chloride of gold of its chlorine; but when the excess of the alkaline salt is a chloride, such an effect is not produced, and the solution is perfect. In the preparation of this toning bath, it is necessary to be very careful to add neither too little nor too much of the chloride of calcium to the chloride of gold; a definite formula cannot be given, from the fact that commercial chloride of gold is very variable as to the quantity of free acid which it contains.

It is better to use the gold bath not too concentrated, the slower the process of toning, the more brilliant the picture remains. The bath loses strength with each print that is toned, but it remains clear and colourless, and can be strengthened by the addition of fresh solution. Before toning, the prints have to be thoroughly washed.

We have treated this subject at some length, because, having recommended the lime bath as possessing certain specific good qualities, we are anxious to give such information on the subject as will enable any of our readers to use it with satisfaction, and because for certain subjects requiring pure blacks and warm neutral tints, it gives better results than any bath we know.

PHOTOGRAPHY AT THE ASSIZES.

A CASE was heard on Tuesday last, before Mr. Baron Bramwell and a common jury, at Croydon Assizes, which will interest photographers, and points a moral as to the importance of having contracts relating to photography, as well as other matters, properly drawn and duly stamped.

The action stood on the case list as *Fry v. Birnstingl*, and was brought to recover the price of goods "sold and delivered," although a verdict was eventually obtained on a different issue. The defendant pleaded "never indebted." The facts of the case, as stated by the plaintiff's counsel, Mr. Serjeant Parry, assisted by Mr. J. C. Matthews, were as follows:—In the summer of 1861, Mr. Birnstingl, a dealer in fancy goods, in the course of some speculations in photography, entered into an arrangement with Mr. Samuel Fry, whose name is well known to our readers, to take fifty negatives, instantaneous sea views, to be paid for at the rate of a guinea each. They were intended for the printing of transparencies, and it was understood that Mr. Fry was to have the printing, and that his name should appear on each. A somewhat loosely worded contract or memorandum of agreement was drawn out, signed with the initials of each party to the bargain, who each received a copy of the document.

We may remark, in passing, that this agreement was not stamped, which was nearly fatal to all the proceedings. Mr. Fry's copy was unfortunately lost by having been placed in the hands of a person, to bring an action on the case, who turned out to be an unqualified practitioner, and from whom it was never recovered. The defendant's counsel put in his copy, and, pointing out that it was unstamped, submitted that the action must be based upon it, and that, being unstamped, it was invalid. If this had been ruled, we apprehend there would have been an end to the action, and whilst each party would have been fined ten pounds, the plaintiff would not only have lost his cause, but have been mulcted in all the costs besides. Mr. Fry's legal advisers were proceeding, however, for goods sold and delivered, apart from this contract, and the judge decided that a contract for goods sold and delivered did not need a stamp.

Amongst the clauses contained in the agreement was one to the effect that the negatives were subject to the approval of Mr. Birnstingl, and a sentence followed about the reading of which some doubt at first existed, as to whether it was "any part of the negatives not approved to be destroyed by Mr. Birnstingl," or, "any print of the negatives, not approved, to be destroyed by Mr. Birnstingl." It was eventually agreed in court that the latter was the real reading.

Mr. Fry proceeded to Ramsgate, and produced about seventy instantaneous negatives, which he delivered to Mr. Birnstingl, and then received from him the sum of twenty-five pounds on account, and a commission to proceed to the Continent to take other negatives.

This was done, but as Mr. Fry could not obtain any settlement of the first transaction, he never delivered any more negatives. He made application, however, from time to time to Mr. Birnstingl to select fifty negatives from those delivered, return the remainder, and pay the balance of the amount due. For some inexplicable cause, Mr. Birnstingl always refused to come to any settlement, alleging that he was quite at liberty to keep the negatives for twenty years, and then, if he did not approve of them, break them all. No settlement having been obtained, nor any negatives having been returned, this action was brought to recover forty-eight pounds ten shillings, the balance of the amount due for seventy negatives, at a guinea each. As we chanced to be at Ramsgate when Mr. Fry took the negatives in question, and saw many of them, we were called to depose to their general excellence and the moderation of the charge for them. Mr. Sydney Smyth, having been in Mr. Birnstingl's office when the negatives were delivered, was called to prove their delivery, and to express an opinion of their excellence as instantaneous negatives. He was cross-examined as to whether he had not, at the time, pronounced them bad, but denied that he expressed any opinion on the subject, alleging that as he was engaged on similar work at the time for Mr. Birnstingl, he did not feel called upon to give an opinion of the productions of others.

The defence was to the effect that the negatives were not satisfactory; that the twenty-five pound paid to Mr. Fry was not on account of the negatives delivered, which were declared to be bad at the time, but a payment in advance, to enable Mr. Fry to go to France to get others in their place; and that, as no others had been delivered, the faulty negatives were retained as some security for the repayment of the money advanced. In support of this there was no evidence but the defendant's statement, and the production of the receipt for the twenty-five pounds, which was in the form of an I.O.U., and stated that the money was in advance for negatives ordered.

Some of the negatives and some transparent positives were produced in court, and a good deal of amusing blundering occurred both at the bar and bench from the misapprehension and misuse of technical terms.

Mr. Serjeant Parry was interrupted in the course of an able closing speech for the plaintiff by the Judge, to point out that as the contract was for fifty negatives the action could not be brought for seventy; and as no especial fifty had been selected, the action for goods sold and delivered could not be sustained. To prevent a failure of justice, however, he would permit the plaintiff to amend. A special court was then prepared, bringing the action for damages for non-acceptance of the negatives.

Mr. Joyce, on behalf of the defendant, declining to plead to this new count, the learned Judge said the case became virtually an undefended action, and must go to the jury on the general plea on the record.

The learned Baron, in summing up, pointed out that it was absurd to suppose that the defendant had given Mr. Fry twenty-five pounds as an advance on a new commission, if he were convinced that the negatives already delivered were worthless, and suggested that, although the receipt was singularly worded, a person receiving a sum like twenty-five pounds was not always very particular as to the wording of the receipt he was called to sign. If the jury believed the plaintiff's statement, that the money was received on account of the negatives already delivered, and that no objection was taken to them at the time, the only question which remained for them was the amount of damages to be awarded for the non-acceptance or rejection of the negatives in a reasonable time, and for their detention until now. The learned judge endeavoured to gain some data as to the depreciation suffered in consequence of the decreased demand for instantaneous stereoscopic views. He asked our opinion, but we were unprepared to name at a moment's notice any definite sum. Other witnesses were unable to throw light on the question. The defendant's counsel incautiously said they would willingly take five shillings each for the negatives; upon which his lordship said, in that case the negatives had suffered a depreciation of sixteen shillings each, and after some further observations, left the matter to the jury.

After retiring for about three minutes, the jury returned with a verdict for the plaintiff, damages twenty-five guineas. By this verdict we understand that the negatives, not having been accepted, become again the property of Mr. Fry, together with the sum of twenty-five guineas, in addition to the amount already received, as damages for non-acceptance, or rejection, of the negatives delivered, within a reasonable time.

We ought here to add, that the attorney for the plaintiff in this action was Mr. W. W. King, an enthusiastic amateur photographer, and member of each of the three photographic societies in London.

In concluding, we cannot help urging upon photographers the importance in all cases of contract of having the terms clearly stated in writing, and of having the document stamped. These precautions are necessary in all agreements, but in the case of commercial contracts relating to an art like photography, which may eventually come for decision before persons entirely unacquainted with the details of the art, it becomes doubly imperative. We scarcely remember

an instance of an action relating to photographic dealings which might not have been avoided had a clearly stated and duly stamped agreement been made at the outset.

Scientific Gossip.

MOVEMENTS OF CAMPHOR ON WATER—NEW TEST FOR GREASE AND IMPURITIES.

WHEN small pieces of camphor are dropped on to the surface of a glass of water several curious phenomena may be observed. They immediately commence to rotate, and move about with remarkable energy, varying sometimes in rapidity, but usually conducting their gyrations in a strange and erratic manner. This is an experiment which most of our readers must have seen performed at some time or other. In order to obtain the best effects, some precautions are necessary: thus the camphor should be tolerably pure; the piece employed should be cut and separated from the larger lump with a perfectly clean instrument, and contact with the fingers should be scrupulously avoided. Moreover, the glass should be quite clean and the water pure. When these conditions are satisfied, the phenomena are really very striking, and well merit more attention than is generally devoted to such things. Several physicists have observed these curious motions of camphor; amongst others may be specially named Mr. Tomlinson and Mr. Lightfoot. The former gentleman has been attracted more to the physical phenomena involved in the movements, whilst Mr. Lightfoot has principally studied the chemistry of the subject. Each is of interest, but it is to some results recently found out in respect to the latter branch of inquiry that we desire at present to draw our readers' attention. If, instead of using a torn or cut fragment from a lump of camphor, one or two fine crystals are detached with a clean needle-point from the cork of a phial in which camphor is kept, and these are let fall on to clean water, they at once begin to move about with wonderfully increased rapidity, darting away in various directions, as if shot from some miniature engine of propulsion; or, as if endowed with life and a will of their own, they feared the searching eyes and magnifying lens of the observer in their endeavours to find a hiding-place; each crystal quivering and rocking on the water with an apparent high degree of indignation at its forced contact with the humid surface. This fury gradually diminishes, and a regular dance begins with the various additional particles that may be introduced to the company. They select partners, to some of which they will seem to cling with pertinacity, whilst others will either remain indifferent or, if attracted, will only stay a very short time in embrace, detaching and wandering again in search of more congenial floating associates. The explanation which Mr. Lightfoot gives of these movements is the emanation of a vapour from the volatile camphor. This vapour has a very low tension; the water upon which it floats being capable of dissolving and diffusing this vapour more readily in certain directions of the crystalline axes, thereby removes sufficient vapour pressure at those points for the opposite side to drive about (by recoil) the nicely suspended particle. Thus, if we place on water several well-defined hexagonal plates and prisms of camphor, the mutual attraction of the particles will be noticed to be stronger in the direction of the angles of the hexagon, accompanied by a decided preference for one of the axes, generally the longest in prismatic crystals. In certain positions two crystals of camphor will attract each other, whilst in other situations there is a mutual repulsion. It will sometimes happen that two crystals of camphor may be thrown on the water and not have any tendency to locomotion. When this is the case a continual trembling or vibration will be noticed in the crystal. When two such stationary vibrating crystals come in contact by attraction, immediately an eccentric, irregular change of place takes place, as if the force agitating each previous to the grouping produced a new resultant force in obedience to which the combined crystals move.

In our description of the method of separating and placing the camphor on the water, we laid some stress on the fact that everything should be quite clean, and that the fingers should not touch the camphor in any stage. The reason of this is obvious. If, whilst camphor is actively moving on water, the most minute particle only of certain greasy substances touch the water, instantaneously, as if by some magic shot, the camphor is deprived of all motion. The scene of previous activity is changed into the immobility of death. This curious property has been made use of by Mr. Lightfoot to detect grease in quantities so extremely minute as would appear almost fabulous. Thus, if we take a clean needle or pin, and only pass it through the hairs of the head, or cause it to touch the side of the nose or the surface of the forehead, and then insert the point of the needle just under the surface of the water, where camphor is rotating, it will instantly stop it; for camphor cannot be made to rotate on water containing the most infinitesimal portions of grease. Mr. Lightfoot has made use of this test in a most ingenious manner to distinguish between the two different methods of dyeing cloth with madder and with garancine. It is difficult and often impossible for calico-printers and merchants to distinguish between the two, and as the garancine dye is more fugitive than the first, and also of less intrinsic worth, it is sometimes substituted for it. There is, however, a slight difference in the process of manufacture—madder-dyed goods are, in one stage of the process, passed through a solution of soap to fix the colour, whilst in garancine-dyed goods the soap is replaced by hypochlorite of lime. By proceeding as follows, it is easy to distinguish between the two kinds of dye:—Let camphor rotate on water in any convenient glass vessel, as previously described, then immerse a small strip of the cloth to be tested. If the rotation stops, we infer the presence of soap, and conclude it to have been dyed with madder. But if, on plunging in the small piece of cloth, the rotation is not stopped, we then arrive at the conclusion that garancine was the dyeing material used. This plan of testing is more decisive in doubtful cases, if the pieces of cloth are, with as little handling as possible, boiled, each in a small glass beaker, and, when cooled, bits or crystals of camphor are dropped on the surface of each sample liquor.

Possibly our readers may never require to test pieces of cloth for a particular dye in the above manner; but they can frequently make use of the test with advantage in detecting the presence of grease in materials which more immediately concern them. What more necessary, for instance, than to have the cloths and leathers with which their glasses are cleaned perfectly free from grease? and how frequently are these important, though humble, adjuncts to the laboratory returned home by the laundress in a most unphotographic state of soapiness! A morsel of camphor in a glass of water will instantly show whether any cloth is fit to give the final polish to a glass plate, by its not arresting the movements, or whether it is dangerously greasy, as shown by its stopping the rotations. Again, it is not so commonly known as it ought to be, that distilled water frequently contains more than a trace of grease. Sometimes this can be recognised by the odour; but if this does not detect it, or if the photographer assumes that, because *distilled*, it must necessarily be pure, endless troubles and vexations may be entailed upon him, and fogging baths and stained plates will become the rule, instead of the exception. Before using the distilled water for any photographic purpose, it should always be tested by pouring a little into a wine glass, and then dropping a fragment of camphor on to the surface. The degree of purity of the liquid is at once shown by the energy of the movements. So delicate is this test, that the author has proved the presence of grease in water taken out of the sea about a mile from the pier at Southport (attributed to the sewage emptying itself near to the pier), whilst water taken out of the Irish Sea about sixty miles from Southport was perfectly free from any greasy matter whatever.

DRY COLLODION—THE TANNIN PROCESS.

BY G. DE VYLDER.

IN the month of April last MM. Teissère and Jacquemet communicated to the Photographic Society of Marseilles the Dry Collodion process they employ with so much success, and which, in the hands of amateur photographers much less skilful has led to the most remarkable results.

We are of opinion that we cannot too much draw attention of photographers to the importance of dry processes.

Wet collodion appears to have acquired the monopoly of producing portraits. But to dry collodion will belong, sooner or later, the monopoly of producing views. Now the vocation of the photographer is not to produce portraits exclusively : that in some respects is the commercial section of the art. The true mission of photography, in our opinion, essentially artistic, we might say civilizing, is the popularizing of the master-pieces of art, so that the idea of the beautiful may descend to the million, and plant the fruitful seed of the idea, of the good and the true, and the representation of scenes from nature, so that the knowledge of distant countries may be prohibited to the many, and that the majority may share the pleasures enjoyed every hour by those who travel wherever they list, with the sole object of seeing, learning, and knowing.

If it be true that wet collodion *can*, up to a certain point, suffice to the reproduction of pictures and engravings, it is indisputable that for taking views from nature, it is altogether insufficient, or rather, much too embarrassing on account of the baggage and apparatus required to work it in the field.

However ingenious and complete the portable laboratories invented may be, the necessity for developing on the spot immediately, the employment more or less simplified of developers, intensifiers, and fixing agents—will always prove serious obstacles to these apparatus becoming popular and generally adopted—which is also a matter of regret.

Let us, however, hasten to admit, so as not to offend the exclusive partizans of wet collodion, that this necessity for obtaining the first negative upon the spot, is sometimes an advantage in this sense, that if the negative has not the requisite qualities for giving good positives, enlarged or not, we can obtain another immediately without difficulty.

But this advantage over the dry process will no longer exist from the time that the latter becomes sufficiently certain, and perfect to furnish at once, a picture in the desired condition. It is from this point of view especially, that we call the attention of photographers to dry processes. He who succeeds in supplying a dry collodion more sensitive than any known at present, which will simplify manipulations without compromising the final result, will render a real service to the art.

In this respect, Major Russell has nearly solved the problem : by making known the properties of the preservative coating of tannin, he has, in great measure, caused the great difficulties of the albumen process to disappear, he has also simplified the process, and made an immense step in advance in the taking of photographic views.

But it must be admitted that in the pamphlet in which Major Russell describes his process, the explanations he gives are not calculated to encourage experiments. He who for the first time undertakes the reading of the "Tannin Process" is, in some measure, intimidated by the minute details, by the precaution to be taken, the accidents to which he is liable, and the causes of failure, of which the author is not sparing. It demands no small stock of courage, to proceed, without deviation, to the end of this labyrinth of details, and a certain amount of perspicacity to separate what constitutes the essence of the process, from the material conditions by which to accomplish its execution. To cause this process to be adopted and become popular, only its peculiar characteristics should be given, and the leading features of its manipulations, and leave to experience the care of regulating the precautions of detail.

These remarks of course apply only to the form given to the pamphlet, and not to the process itself, for which we have perfect sympathy. We only think, contrary to the opinion of M. Girard, that in the explanation of the process, useless details are sometimes misplaced ; those to whom photographic treatises are already familiar, more or less, very well know the infinite precaution which must be taken at every moment, and moreover that a failure in this, as in all other things, teaches more than any amount of written explanation.

We repeat that in rendering sincere homage to the valuable discovery of Major Russell, and in acknowledging the services it is called to render, we admit that there is a necessity for explaining it in the clearest manner, and in the most inviting also.

It is with this object in view that we have solicited and obtained permission to give in our course of instruction at the School of Industry, and to publish in the *Bulletin Belge de la Photographie*, the tannin process which M. Jacquemet has wished us to communicate the explanation is ; given with such simplicity and clearness as to dispel from the first all idea of failure. Candidly, we cannot too much exhort amateurs to try this process ; we are convinced that they will succeed at the first trial.

In our experiments we have employed the autopolygraph invented by M. Vidal, an apparatus less known than it deserves to be, but which is undoubtedly destined to become very popular. It is very simple in its working ; and the bulk is reduced to the smallest compass, it presents therefore all the advantages we look for in an apparatus with which we have to traverse plains, or climb mountains. It may be objected that the negatives it yields are too small $3\frac{1}{2}$ inches by 4 inches. But these are the dimensions of stereoscopic pictures so very popular at the present day, and if they can afterwards be enlarged by a process as simple and ingenious as that indicated by M. Testelin, in a pamphlet he published some years ago, it will be possible for any one possessing a whole plate apparatus to obtain with the greatest facility positives or negatives enlarged from the negative furnished by the autopolygraph.

We now arrive at the explanation of MM. Teissère and Jacquemet's process, which although, it differs but slightly from that of Major Russell, deserves, nevertheless, to be regarded as a special process.

1. *Collodion*. Every collodion which yields good results in the wet process may be employed in this. Remarking that it must contain at least 1 per cent of iodide and 1-3rd of bromide. We generally make use of the collodion described by M. Van Monckhoven in the last edition of his "*Traité de Photographie*," lightly increasing however, the quantity of iodides and bromides. The following is the formula of this collodion :—

Ether	60 drachms.
Alcohol... ..	40 "
Pyroxyline	1 drachm
Iodide of cadmium	0.75 drachms
Iodide of ammonium	0.50 "
Bromide of ammonium	0.40 "

MM. Jacquemet and Teissère have undertaken a series of experiments concerning the employment of a special collodion, more sensitive than ordinary collodion. But as these experiments are not yet completed, and as it is also but just that to the inventors alone should belong the honour of initiating the public, we abstain from mentioning even the principle upon which these experiments are based.

The plates are not gelatined. This is a step in advance, for the application of gelatine is a delicate and difficult operation.

The collodion is therefore directly applied upon a well-cleaned plate ; taking care to leave no corners. To cover the plate easily, we hold the plate with a tuft of cotton slightly moistened with distilled water.

2. *Sensitizing.* The silver bath to sensitize the collodion plate is composed as follows:—

Distilled water	100 parts
Crystallized nitrate of silver	...	8 "	
Glacial acetic acid	...	2 "	

The operation is conducted as follows: the sensitizing bath may contain two plates at once, a light border of gutta-percha separating them, so that one plate cannot slide upon the other. While we are collodioning a second plate, the first is sensitized, and when the second is put into the silver bath, withdrawing the first, which is immediately put into the first washing bath, and so with the rest. The first operation is thus performed rapidly and in good condition.

3. *The Washings.* As the plates are withdrawn from the sensitizing bath, they are placed in the first bath of filtered distilled water, where they must remain until the greasiness disappears. When the twenty plates of the autopolygraph are collected in this bath, they are passed successively, one by one, into two other baths of ordinary filtered water, and, lastly, in a fourth bath of distilled water, also filtered. When all the plates have been collected in this last bath, and we are about to apply the preservative solution, a light stream of distilled water is poured over each plate, in order to remove the last impurities that may still adhere.

For these washings we employ rectangular zinc dishes, covered internally with a coating that cannot be attacked (manufactured by M. Deltenre). The middle of the dish is occupied with a raised partition, so that it forms a sort of continuous channel upon the edges of which the twenty plates rest. The dishes are 24 inches long by 8 inches wide.

4. *Application of the Preservative.*—The tannin solution is formed of

Distilled water	100 parts
Tannin	...	3 "	
Alcohol	...	5 "	

To prepare it we put the tannin into the water and it is generally very quickly dissolved; then it is filtered several times, three or four at least, and, lastly, some clear alcohol is introduced into the liquid. The object of the latter is to make the liquid penetrate the collodion film more readily; it also assists in making the solution keep longer without decomposition. It should be noted that the alcohol must not be added until the solution of tannin is filtered, for the alcohol dissolves certain resinous substances always found mixed with tannin which are insoluble in water.

We then take two lipped glasses, of very different forms, and numbered, so as not to confound them with each other, and pour into each a certain quantity of the solution of tannin.

After the first bath, withdrawn from the last washing bath, and rinsed with a stream of distilled water and drained, we pour upon it several times the contents of the glass No. 1 until the liquid has well penetrated the film, that is to say, until it has covered all parts of the plate equally; next, this tannin application being complete, the plate is drained, and then the contents of glass No. 2 at once, and the excess is poured off into glass No. 1.

We then put the plate to dry, collodion side downwards, resting by one corner on a piece of blotting-paper. But according to the recent experiments of MM. Teissère and Jacquemet, the sensitiveness of the plate is greatly increased if after having poured on the tannin the plate is washed in a stream of distilled water, so as to free it from the excess of tannin. It is important not to touch the collodion or the silver bath with the fingers more or less soiled with tannin; to avoid any accident, it is well to first sensitize all the plates, before proceeding to the application of the tannin.

After drying for seven or eight hours, under the ordinary conditions of heat and moisture, the plates are ready for use. They are then placed in the upper chamber of the autopolygraph, or in a grooved box, hermetically closed. The sensitiveness of these plates continues a very long time, as much as two or three months, but they eventually become mouldy.

5. *Exposure.* The autopolygraph we employ is furnished with a simple quarter-plate objective; with the smallest diaphragm the exposure will be—

For a lens with 4 inches focus,	1 to 1½ minute.
Do. do. 5½ do.	2 to 2½ minutes.
Do. do. 7½ do.	3 to 3½ do.

6. *Development.* It is important to delay the development as little as possible, for the plates quickly lose the faculty of retaining the image. Here, if we do not deceive ourselves, is the starting point of a theory explanatory of the formation of photographic images, the principle of which was first announced by M. Vidal.

Before commencing the development, the edges of the plate must be coated, by means of a small pencil, with a very dense varnish, composed, for example, of—alcohol, 100 parts, shellac, 20 parts; two coats must be applied. After drying, each plate is immersed for a few moments in water, and afterwards uniformly moistened with the sensitizing solution. The plate is next immersed in a flat dish containing a sufficient quantity of the following developing solution:—

Distilled water	200 parts.
Pyrogallic acid	1 part.
Glacial acetic acid	10 parts.

It must be continually shaken to avoid deposits.

The most delicate part of the process now begins, at least under certain circumstances. The development may exhibit three distinct characters:—

1st. The proof comes out well; the whites well preserved, and all the details distinct and clear; we have then only to add gradually a few drops of a weak solution of nitrate of silver, so that the blacks may assume the intensity required in a good negative.

2nd. The picture comes out rapidly, with a tendency to fog; it has been exposed too long. We then add a few drops of acetic acid, without nitrate, to check the development. Towards the end, add, if necessary, a little silver, to bring the picture to the desired tone.

3rd. The picture comes out slowly; the large lights only are distinct; there is no detail; the exposure has been insufficient. Then add to the liquid in the dish two or three drops of a concentrated alcoholic solution of pyrogallic acid (for example, one drachm to ten of alcohol, which serves very well for the preparation of the strengthening solution in the wet collodion process); add, also, one or two drops of a weak solution of silver, and allow it to act. If the addition is insufficient, increase the dose until the details come out, then strengthen, if necessary, by adding acetic acid and silver.

During this operation it may happen that the liquid becomes muddy; it must then be quickly rejected, and replaced by a fresh quantity of the original developer.

At the conclusion of these manipulations, longer and more difficult to describe than perform, the plate is carefully washed, and fixed as usual, but with hyposulphite of soda. After washing, a coating of gum-arabic solution is applied, and when the plate is quite dry, it is varnished. The negative is now finished.

As the reader may now judge, the process is far from being difficult or complicated; and success is pretty certain. And we again urge amateurs to try it. If they carefully follow the directions here given, it is quite certain that their efforts will be successful.—*Bulletin Belge de la Photographie.*

MACROPHOTOGRAPHY, OR THE ART OF TAKING ENLARGED PICTURES OF PHOTOGRAPHS.*

THE NEGATIVE FOR ENLARGEMENT.

THE size of the negative will have to depend on the diameter of the condenser; if this be nine inches, a one-sixth plate will be large enough, the object being to get the negative as

* From *Humphrey's Journal.*

near the apex of the cone of concentrated light as possible, and in such a position as to be totally covered by the conc.

THE QUALITY OF THE NEGATIVE.

The negative suitable for the solar camera must be very bright, well-defined, and quite clear. The glass must be thin, perfectly flat, and homogeneous. The negative effect need not—in fact, must not—be carried on to the same extent as for positive printing; it is but a trifle in advance of the ambrotype. If there should happen to be the slightest quantity of fogging—that is, reduction on the transparent parts—it will be necessary either to take another negative, or to clear off the fogging. This is effected by flowing the plate with a dilute solution of iodine in iodide of potassium until the picture turns slightly cream-coloured; the plate is washed, and then flowed with a solution of cyanide of potassium, which dissolves the newly-formed iodide of silver, and thus clarifies the negative. If satisfactory, wash and dry, but apply no varnish.

Previous to fixing the negative in the plate-holder, adjust the lens to its right position, so as to bring the *focus of the actinic rays* immediately on the optical centre of the last or front lens of the combination. It is by this means alone that the best enlarged picture can be obtained.

HOW TO FIND THE POINT WITH ACCURACY WHERE THE LENS IS TO BE PLACED.

Ascertain the focal length of the condenser by finding the distance of its burning point from the glass; then, when the tube is screwed out to the extent of its play, measure the distance from the face-plate, in which the tube is fastened, to the front lens; subtract this distance from the focal length of the condenser: the difference will give the distance of the condenser to the outside of the camera nearly, or to the part upon which the face-plate of the tube is to be screwed.

More accurately the same result can be obtained by interposing the tube in the condensed light, and by moving it backwards and forwards until the focal or burning point is just on the outside of the front lens; let an assistant measure this distance from the outside of the camera, and at this distance fix the tube permanently. Whilst doing this the greatest care is required to make the axis of the condenser coincide exactly with the axis of the tube.

This is the first rude adjustment. The second adjustment consists in bringing the actinic focus so as to coincide with the optic centre of the front lens. Screw back the sliding part of the tube, and turn on the sun; the luminous focus will be quite visible in the dark space behind the camera. Now insert a piece of deep violet-coloured glass between the condenser and the objective, so as to intercept all the colours of the luminous cone excepting the violet, and ascertain where the violet cone comes to a focus. Screw the tube out until this focus is just in front of the anterior glass; then, knowing the thickness of the front lens, advance the tube until the blue focus is in the middle of the front lens. This will be the *final and permanent adjustment* of the tube in reference to the condenser. Mark this position by a line on the brass-work, in order that the tube can be adjusted at a moment's notice when required to be used.

The negative-holder is movable by means of a screw, so that it can be brought into focus upon any screen on the other side of the tube. Whenever this operation of focussing is to be performed, insert the violet-coloured glass so as to focus in reference to actinism, and not to luminosity. By this means the luminous picture on the screen (that is, when the violet-coloured glass is removed) may not be quite sharp, but the printed picture on the paper will be sharp and beautifully defined.

The same mode of proceeding may be followed with the ordinary camera, where there is any doubt of the correction of the tube for actinism. Place in front of the tube a plate of violet-coloured glass every time you focus.

As soon as the negative is in its place, and accurately focussed actinically, fix the prepared paper on the screen in

its place. In order to preserve the paper perfectly flat and smooth, sponge the back with a wet sponge, and after it has thoroughly expanded, and lies uniform and without undulations, go round the edge to the amount of half an inch, on the same surface that has been sponged, with a thick solution of gum arabic; attach the paper so prepared to an even plate of glass or hard drawing board of somewhat smaller dimensions than the paper, and allow it to dry. When dry, all the corrugations and undulations will have disappeared; the paper will be smooth and flat, and ready to receive the image, supposing naturally it has been already sensitized in the silver bath. If this operation has been omitted or neglected, the silver solution can be very expeditiously poured upon the surface and spread with a pad or tuft of cotton wool until the film is uniform. The excess of silver is then removed, and the plate is reared on one corner over a wine-glass to receive the drippings.

When dry, it is placed in the focus of the negative, and the sun is turned on. By means of the two screws on the solar camera, the sun's light is maintained in its position during the whole operation. Printing on albumenized paper by the solar camera is a tedious operation, requiring sometimes several hours before it is complete, and sometimes even a day or two, by reason of the cloudiness of the sky.

Where this sort of printing is practicable, as is the case generally in our own country, the results are the best. Printing by development, however, is more reliable, because it is altogether independent of the condition of the sky, whether cloudy or cloudless. Several processes by development may be found in text-books devoted to the subject. I will insert in this place the one practised by Blanquart-Evrard, whose prints have been so much admired.

BROMO-IODIZING BATH FOR PAPER.

Water	12 ounces.
Gelatine	1 drachm.
Iodide of potassium	1 drachm.
Bromide of potassium	15 grains.

Immerse the papers in this bath, as many at a time as it will contain, and keep them there for two or three hours. The bath can be used over and over again until exhausted. The papers are then taken out and hung up to dry. As soon as they are dry, they may be preserved in a portfolio for use.

Previous to being sensitized they are exposed for a quarter of an hour to the vapour of hydrochloric acid. This operation is easily effected by fixing the papers along the sides and under the lid of a large nearly air-tight box, by means of varnished pins. At the bottom of the box place a saucer containing a handful of salt, an ounce or two of sulphuric acid, and half as much boiling water. Vapours of hydrochloric acid will be generated in abundance, and will thus saturate the paper.

SENSITIZING BATH.

Nitrate of silver	1 ounce.
Distilled water	14 ounces.
Nitric acid to give it an acid reaction.	

Let the papers float in this solution for ten minutes. By decomposition they will now contain the iodide, the bromide, and chloride of silver. After sensitization they are allowed to drain, and then dried either by pressure between folds of bibulous paper or by suspension in the dark room.

The exposure required will vary from a couple of seconds to half a minute beneath a negative, and longer than this on the screen of the solar camera. When the image is just visible the printing has been carried on long enough.

DEVELOPMENT.

The picture is brought out by immersing it in ordinary gallic acid bath, at a temperature of 80° Fahrenheit, and by keeping them there a quarter of an hour or more as circumstances require. The bath or dish must be large enough for

many pictures at a time; these are kept in motion all the while. They assume a disagreeable colour, and become covered with spots, which are removed by the operations afterwards. As soon as the depth of the shade is sufficiently intense, the prints are taken out, laid one by one on a glass plate, and sponged on both sides, and then immersed in a bath of hyposulphite of soda for five minutes, in which they are toned.

Hyposulphite of soda 1 ounce.
Rain water 20 ounces.

After this they are removed direct into a second bath of hyposulphite of soda of the same strength, and are allowed to remain for twenty minutes, in which they are completely fixed.

The prints are then carefully washed in several waters, and finally immersed in a bath of dilute hydrochloric acid, which removed a yellow deposit and the spots above mentioned. A second washing completes the operation, with the exception of drying and exposing to the action of light for several weeks, which improves the reddish tone by changing it gradually into purple.

These prints will keep for an indefinite time, although toned with sulphur.

A PHOTOGRAPHIC NATIONAL PORTRAIT GALLERY.

PHOTOGRAPHY is daily extending its sphere of usefulness. A new project for its grasp has just been put forth. It is this: that the resources of photography should be applied to the systematic preservation of the likenesses of distinguished individuals. It is true that in the present state of the art prints from the negative plates cannot be depended upon as lasting records, but it is equally true that the negative plates themselves are as lasting as the material (glass) upon which they are taken. Mr. MacLachlan, of Manchester, proposes that the negative plates of great men should be secured and placed in a museum for safe keeping, properly authenticated, attested, and registered by the mayor or other authority of the place where they were taken; and, to provide against accidents, he suggests that in every instance three plates of the same individual should be deposited. This can easily be done, as the original one can be always reproduced at pleasure. He proposes "securing three plates, in order that one may be kept sacredly within the institution, and the other two be lent at the discretion of the authorities in charge,—for instance, to any author of eminence for book illustration: and by that means the memories and images of those who have been great and have passed away would be transmitted faithfully to all posterity. In almost every instance there would be several portraits of the same individual in different museums in the country, affording a still greater security for their permanent preservation. All local celebrities might be taken in their own towns and deposited in the museums of their respective localities; and should a time arrive when their genius became acknowledged by the world, then they might claim a place in our Great National Museum." What would we not now give for such a faithful record of the features of Shakspeare, and many others? The space required for the due storage of many thousands of such plates, carefully numbered and indexed and ready of access, would be very small. A cubic foot of space would hold several thousands. The cost of procuring such plates would be very trifling. Indeed, in a large majority of instances, the photographers would be willing to deposit negatives in return for the privilege of having sittings from distinguished individuals, whose portraits they would thus be enabled to sell for their own advantage. Hereafter, when the art of burning in the likeness on glass after the manner of enamels (some very beautiful specimens of which were exhibited in the late International Exhibition) is brought to perfection, we may dispense with the negatives, and a collection of miniatures on enamel may be made, which will indeed form a real national portrait-gallery.—*Athenæum*.

A PHOTOGRAPHIC GLANCE AT MELROSE FOUNTAINS, NORTH WALES, &c.

BY THE REV. J. C. BROWNE, M.A., EMMANUEL COLLEGE, CAMBRIDGE.

THE time having arrived when our brethren are starting hither and thither, with camera on shoulder—more, we trust, for the sake of enlightening the mind, and adding to their stock of health and art, than simply to bring back mementoes of places visited—I will give you a short account of my last summer's tour.

I started from Edinburgh about the middle of July, under the most unfavourable auspices in point of weather, and in an hour and a half or so found myself comfortably located at Melrose. Hard as it rained I could not refrain from going to have a peep at the dear old Abbey, just to see that it really was there, in case I might find it levelled to the ground in the morning; for Admiral Fitzroy had shaken my previous faith in him as the "photographer's friend," by ordering the cone and drum to be hoisted at Leith Harbour.

Morning came, and with it a bright, clear sun and a fresh breeze, and I saw that all was right for my work that day. Breakfast over, I sallied forth, paid my shilling admittance to the Abbey, and began at the lovely east window, towards the sacred mullions of which—clearly revered by the devouring chisel of Time—I planted my Horne and Thornthwaite's double lensed stereoscopic camera. The wind, however, began to rise to such an enormous extent that I was obliged to place some of the scattered fragments of stones lying about the graveyard upon the camera to steady it, and withal to stand back to the gale with an open umbrella. It was hard work; but, nevertheless, I exposed four tannin plates, and all but one turned out good—the delinquent having clearly had a good shaking in the wind. Next day was as bad; so I amused myself with standing above my knees half the day in the Tweed, and was rewarded with a few trout. The day following was more after my sort, and I succeeded in getting a series of views from east round by south to south west, and a couple of interiors, and bade the place "good bye."

On Sunday, after church, I walked to Abbotsford to see the place; but being too far to take another journey with my camera over there, the next day, Monday, saw me at Carlisle. Thence proceeding to Windermere, I stayed one night there, and the following at Ambleside; but so little presented itself in a stereoscopic point of view, that I made my way through Leeds to Ripon, where I stayed at the "Angel" for four days.

Through the kindness of Captain Smith I obtained a key to Pountains Abbey, and was there every day and all day, insomuch that I never even had a peep at Ripon Cathedral. During my visit there I scarcely once saw the sun, and nearly all my plates were exposed in drizzling rain; however, tannin was my friend, and I managed to get some third class pictures.

Off to Chester, through Manchester. Finding myself in a cathedral city, the temptation of choral services overcame me, and I postponed setting foot in Wales until the Monday morning. Starting early, I reached our rendezvous—the Castle Hotel, at Conway—where I found two old college friends, who, tired of waiting for my train, and afraid of missing the coach, were already hard at work at a nine o'clock breakfast. The coach drew up. We had not previously booked our places, and consequently were compelled to lose the scenery of the Vale of Llanrwst by sitting for some hours in the miserable inside. Doubtless it was a novel sight for our Welsh "chaw-bacons;" but legs six feet long would not wholly go inside, and, not daring to trust them amongst the rest of the luggage, we showed about three feet of ash out of each window.

Arriving at Bettws-y-Coed, we feared we were "done," the principal inn being full to a bed, and people already on foot

in search of lodgings, but none to be got. However, by some good luck, we managed to get to the other hotel—the Waterloo—just as two bedrooms were being vacated, and we booked ourselves for a week or so. Of all the places we visited we preferred this, their being no fewer than a thousand and one pictures to be taken within a radius of a couple of miles.

The chief places for photographers to visit, and such as they must not omit taking, are—the old ivy-grown bridge at the Toll-gate over the Llugwy, views both up and down; the Miner's Bridge, higher up, towards Capel Curig; and the Swallow Water Falls, higher still. The Miner's Glen is a lovely spot, and Mr. Hornby got some capital $7\frac{1}{2} \times 4\frac{3}{4}$ collodio-albumen pictures of it.

Turning out of the Waterloo to the right hand, a bridge spans the river—a single arch of iron—and through the whole length of the arch is the following inscription:—"This arch was constructed the same year the battle of Waterloo was fought." Of this bridge, though a modern erection, a very artistic picture can be got about thirty yards from it, towards the Lledr Valley on the Bettws-y-Coed side.

Crossing the bridge take the first turning to the right, and, just before you arrive at a stone bridge, one of Nature's real nooks presents itself, on the left-hand side of the road, in the shape of a fountain, about six feet, cubed, overgrown with briars, brambles, &c.; but it wanted something to fill up the interior, and so I planted some ferns, and obtained a very good picture in twenty-two minutes on a dull day.

Instead of crossing the bridge, which would take you to the Lledr Valley, I think the road straight on more interesting; and some very good rocky pieces can be got by the side of the gorge through which the Conway flows. The celebrated Conway Falls are a little higher.

From Bettws-y-Coed we proceeded through Capel Curig to Beddgelert—a lovely spot, near which is the grand Pass of Aberglaslyn, with its renowned Pont. A whole day may be profitably spent in its vicinity. The windings of the river are very pretty; also some good thatch-grown cottages and a rustic bridge on the right-hand side a few yards up from the road, entering by a sort of stone-grinding mill.

From Beddgelert we made the ascent of Snowdon without a guide, our party consisting of Mr. D. Hornby, his brother (Mr. T. Hornby), and a gentleman from Preston (Mr. W. Perfect). We ascended in a fog; but Nimbus permitted us a few bright moments at the summit, and we got some first-rate stereographs of the Cairn and public houses on the top. Descending we obtained some glorious sunset views of Anglesea, the Tubular Bridge, and down along the eastern coast of the country.

Leaving Bettws-y-Coed we took a trap to Carnarvon, and just caught the train to Menai Bridge. The Nant Mill must not be omitted on the road to Carnarvon. It was very wet during our stay at Menai Bridge, but we got some very fair pictures of the Suspension and Tubular Bridges. Passing Bangor we returned to Conway, thence to Llandudno and Great Ormeshead, and so we found ourselves once more at Chester.

I have omitted to mention that one day at Beddgelert we walked round by the Gwynant Valley, through the Pass of Llanberis, to the town, where we took views of the famous falls and slate quarries.

We proceeded to Manchester, and then shot straight across England, where we visited Mr. Thomas Hornby for a fortnight; thence to Scarborough, where we also obtained some very fair pictures—one of Mr. Hornby's $7\frac{1}{2} \times 4\frac{3}{4}$, of the Swiss Cottage in the Cliff Company's grounds, being only equalled by a magnificent negative afterwards taken at York of the Galilee door of the Minster.

At York we parted company, hoping at no distant period to revisit North Wales and its bold scenery.

The account of a successful tour ought certainly to have appended the working of the process. I used some collodion made by Lennie and Co., opticians, &c., Princes-street, Edinburgh. No previous coating of gelatine. Sensitised is

an ordinary 35-grain bath, nearly neutral; thoroughly washed the plate, first in distilled water, then in salt water, about one grain to the ounce, and then thoroughly under a tap. I then swilled the plate with distilled water, and poured on and off once or twice some of the following solution:—

Tannic acid	15 grains
Crystallized coffee sugar	15 "
Distilled water	1 ounce.

Filter when dissolved.

When the plates are covered and drained set up to dry.

To develop I placed round the plate about one-eighth of an inch rim of benzole and white wax (saturated) which dries in two or three minutes. Then covering the plate with pyrogallic acid, three grains to the ounce, I afterwards added one drop of—

Nitrate of silver	10 grains
Citric acid	10 "
Distilled water	1 ounce,

until all detail was out, then added this silver solution until sufficiently intense, and fixed with cyanide. The film must slowly dry, otherwise, in some few cases, I found it split up into ribbons.

DOINGS OF THE SUNBEAM.*

WE have learned many curious facts from photographic portraits which we were slow to learn from faces. One is the great number of aspects belonging to each countenance with which we are familiar. Sometimes, in looking at a portrait, it seems to us that this is just the face we know, and that it is always thus. But again another view shows us a wholly different aspect, and yet as absolutely characteristic as the first; and a third and a fourth convince us that our friend was not one, but many in outward appearance, as in the mental and emotional shapes by which his inner nature made itself known to us.

Another point which must have struck everybody who has studied photographic portraits is the family likeness that shows itself throughout a whole wide connection. We notice it more readily than in life, from the fact that we bring many of these family portraits together, and study them more at our ease. There is something in the face that corresponds to *tone* in the voice,—recognizable, not capable of description; and this kind of resemblance in the faces of kindred we may observe, though the features are unlike. But the features themselves are wonderfully tenacious of their old patterns. The Prince of Wales is getting to look like George III. We noticed it when he was in this country; we see it more plainly in his recent photographs. Governor Endicott's features have come straight down to some of his descendants in the present day. There is a dimpled chin which runs through one family connection we have studied, and a certain form of lip which belongs to another. As our *cheval de bataille* stands ready saddled and bridled for us just now, we must indulge ourselves in mounting him for a brief excursion. This is a story we have told so often that we should begin to doubt it but for the fact that we have before us the written statement of the person who was its subject. His professor, who did not know his name or anything about him, stopped him one day after lecture, and asked him if he was not a relation of Mr. —, a person of some note in Essex County. Not that he had ever heard of. The professor thought he must be,—would he inquire? Two or three days afterwards, having made inquiries at his home in Middlesex County, he reported that an elder member of the family informed him that Mr. —'s great-grandfather, on his mother's side, and his own great-grandfather, on his father's side, were own cousins. The whole class of facts, of which this seems to us too singular an instance to be lost, is forcing itself into notice, with new strength of evidence, through the galleries of photographic family-portraits which are making everywhere.

In the course of a certain number of years there will have been developed some new physiognomical results, which will prove of extreme interest to the physiologist and the moralist. They will take time; for, to bring some of them out fully, a generation must be followed from its cradle to its grave.

* Continued from page 369.

The first is a precise study of the effects of age upon the features. Many series of portraits taken at short intervals through life, studied carefully side by side, will probably show to some acute observer that Nature is very exact in the tallies that mark the years of human life.

The second is to result from a course of investigations which we would rather indicate than follow out; for, if the student of it did not fear the fate of Phalaris,—that he should find himself condemned as unlife-worthy upon the basis of his own observations,—he would very certainly become the object of eternal hatred to the proprietors of all the semi-organizations which he felt obliged to condemn. It consists in the study of the laws of physical degeneration,—the stages and manifestations of the process by which Nature dismantles the complete and typical human organism, until it becomes too bad for her own sufferance, and she kills it off before the advent of the reproductive period, that it may not permanently depress her average of vital force by taking part in the life of the race. There are many signs that fall far short of the marks of cretinism,—yet just as plain as that is to the *visus eruditus*,—which one meets every hour of the day in every circle of society. Many of these are partial arrests of development. We do not care to mention all which we think may be recognized, but there is one which we need not hesitate to speak of from the fact that it is so exceedingly common.

The vertical part of the lower jaw is short, and the angle of the jaw is obtuse, in infancy. When the physical development is complete, the lower jaw, which, as the active partner in the business of mastication, must be developed in proportion to the vigour of the nutritive apparatus, comes down by a rapid growth which gives the straight-cut posterior line and the bold right angle so familiar to us in the portraits of pugilists, exaggerated by the caricaturists in their portraits of fighting men, and noticeable in well-developed persons of all classes. But in imperfectly grown adults the jaw retains the infantile character,—the short vertical portion necessarily implying the obtuse angle. The upper jaw at the same time fails to expand laterally; in vigorous organisms it spreads out boldly, and the teeth stand square and with space enough; whereas in sub-vitalized persons it remains narrow, as in the child, so that the large front teeth are crowded, or slanted forward, or thrown out of line. This want of lateral expansion is frequently seen in the jaws, upper and lower, of the American, and has been considered a common cause of caries of the teeth.

A third series of results will relate to the effect of character in moulding the features. Go through a "rogues' gallery" and observe what the faces of the most hardened villains have in common. All these villainous looks have been shaped out of the unmeaning lineaments of infancy. The police officers know well enough the expression of habitual crime. Now, if all this series of faces had been carefully studied in photographs from the days of innocence to those of confirmed guilt, there is no doubt that a keen eye might recognize, we will not say the first evil volition in the change it wrought upon the face, nor each successive stage in the downward process of the falling nature, but epochs and eras, with differential marks, as palpable, perhaps, as those which separate the aspects of the successive decades of life. And what is far pleasanter, when the character of a neglected and vitiated child is raised by wise culture, the converse change will be found—nay, has been found—to record itself unmistakably upon the faithful page of the countenance; so that charitable institutions have learned that their strongest appeal lies in the request, "Look on this picture, and on that,"—the lawless boy at his entrance, and the decent youth at his dismissal.

The field of photography is extending itself to embrace subjects of strange and sometimes of fearful interest. We have referred in a former article to a stereograph in a friend's collection, showing the bodies of the slain heaped up for burial after the battle of Malignano. We have now before us a series of photographs showing the field of Antietam and the surrounding country, as they appeared after the great battle of the 17th of September. These terrible mementos of one of the most sanguinary conflicts of the war we owe to the enterprise of Mr. Brady, of New York. We ourselves were on the field upon the Sunday following the Wednesday when the battle took place. It is not, however, for us to bear witness to the fidelity of views which the truthful sunbeam has delineated in all their dread reality. The photographs bear witness to the accuracy of some of our own sketches in a paper published in the December number of this magazine. The "ditch" is figured still encumbered with

the dead, and strewed, as we saw it and the neighbouring fields, with fragments and tatters. The "colonel's grey horse" is given in another picture just as we saw him lying.

Let him who wishes to know what war is look at this series of illustrations. These wrecks of manhood thrown together in careless heaps, or ranged in ghastly rows for burial, were alive but yesterday. How dear to their little circles far away most of them!—how little cared for here by the tired party whose office it is to consign them to the earth! An officer may here and there be recognized; but for the rest—if enemies, they will be counted, and that is all. "80 Rebels are buried in this hole" was one of the epitaphs we read and recorded. Many people would not look through this series. Many, having seen it and dreamed of its horrors, would lock it up in some secret drawer, that it might not thrill or revolt those whose soul sickens at such sights. It was so nearly like visiting the battle-field to look over these views, that all the emotious excited by the actual sight of the stained and sordid scene, strewed with rags and wrecks, came back to us, and we buried them in the recesses of our cabinet as we would have buried the mutilated remains of the dead they too vividly represented. Yet war and battles should have truth for their delineator. It is well enough for some Barou Gros or Horace Vernet to please an imperial master with fanciful portraits of what they are supposed to be. The honest sunshine

"Is Nature's sternest painter, yet the best;"

and that gives us, even without the crimson colouring which flows over the recent picture, some conception of what a repulsive, brutal, sickening, hideous thing it is, this dashing together of two frantic mobs to which we give the name of armies. The end to be attained justifies the means, we are willing to believe; but the sight of these pictures is a commentary on civilization such as a savage might well triumph to show its missionaries. Yet through such martyrdom must come our redemption. War is the surgery of crime. Bad as it is in itself, it always implies that something worse has gone before. Where is the American, worthy of his privileges, who does not now recognize the fact, if never until now, that the disease of our nation was organic, not functional, calling for the knife, and not for washes and auodynés?

(To be continued.)

Correspondence.

LIME TONING.

Sir,—Having read with some degree of attention the amusing lamentations of "Cha-meal-ion." I am tempted to tender advice, which, if followed, will not only enable him to bask undisturbed in the sunny rays of success, but will also prove that lime toning is not so difficult a matter as Mr. Hughes seems to think it to be. Use a strong silver bath, and print, if the conditions will admit, in diffused light. Take for each sheet of paper to be toned one grain of chloride of gold, add this to about half the quantity of soda carb. which would be necessary to neutralise the free acid; now pour boiling water (say a pint to five grains of the AuCl³) to drive off excess of chlorine, and lay aside for half an hour when the full quantity of solution necessary may be made by adding cold water. Quantity must be regulated by the exercise of judgment. The saturated solution of chloride and carbonate of lime may now be mixed with it allowing from 5 to 8 minims for each grain of gold employed. Before proceeding to tone the perfect prints, immerse half a dozen or more slightly washed, "roasted," or stained ones. When toned, the bath will be fit for use. Two or three waters previous to toning will be sufficient, that is to say, if the last shows no further deposit of free nitrate. If you think a paper on the chemistry of lime toning would be acceptable to your numerous readers, I shall willingly engage in its preparation; but before doing so, I would ascertain the results arrived at by those who may be tempted to try my method of working.—I remain, yours respectfully,

A PHOTO'S ASSISTANT.

P.S.—I would just observe that should the bath tone very slow, it is a sure sign that too much soda has been employed; if too quick, the alkaline agent must be increased; depth of printing about the same as for acetate bath.

EBOHITE BATHS.

SIR,—Seeing in the last number of the PHOTOGRAPHIC NEWS a letter of inquiry from Captain Dennis Wright respecting the efficacy of dipping baths made of ebonite, I beg you will allow me an opportunity of stating my experience in regard to this matter.

Early in the summer of last year, whilst giving a course of instruction in photography to the officers attending the Royal Artillery Institution, I had frequent inquiries about the chemical efficacy of ebonite, which, on account of its lightness and indestructible character had much to recommend it to the favourable notice of tourists, and others, like my pupils, liable to frequent changes of residence. By way of putting this question to the test of experiment, two ebonite baths were purchased, and used side by side with others made of gutta-percha and glass. I took particular account of their performance, and, as the general result, it was found that the silver solution was more liable to change in the ebonite baths than when contained in vessels of the older materials. The negatives taken were wanting in vigour, and I found, in fact, that metallic silver had become reduced in the form of a brilliant lining over the whole interior surface of the bath, and the solution had acquired an acid reaction.

Shortly afterwards I mentioned this circumstance to Mr. Hugh A. Silver, of the firm of S. W. Silver and Co., Bishopsgate Street, who suggested that the faulty baths might have been prepared from the refuse of the india-rubber manufacture, in which bronze powders and other metallic pigments were likely to be contained. That gentleman told me his firm had recently been engaged in some critical experiments preliminary to undertaking the manufacture of photographic apparatus in pure ebonite, and he kindly offered to place in my hands two of his new dipping baths for comparison with those in common use. With regard to the quality of the india-rubber employed in the composition of the ebonite for these baths it was then stated that all apparatus bearing the stamp of the firm should be made of "virgin gum," and that they were prepared to guarantee that no re-worked rubber should at any time be used in their construction.

Immediately on the arrival of these baths I proceeded to test them in the ordinary way; one bath was started with a fresh solution of nitrate of silver, the other being filled with a supply transferred from a large glass bath, which was acting satisfactorily. By repeatedly testing, at intervals of a week and upwards, I could not detect any deterioration, nor was there any evidence of metallic reduction or liberation of acid; in fact, these vessels answered their purpose admirably, they preserved their shape, bulging but very little, not nearly so much as gutta-percha would have done under like circumstances—their rigidity was, indeed, remarkable, and the solutions left for nearly six months in them remained unimpaired. In regard to weight I found that the bath and air-tight cover, with metal binding screws, hinged support, and dipper complete, weighed, in the aggregate, less than the solution which could be accommodated therein. It should likewise be mentioned that these baths and dippers for 10 by 8 plates were beautifully formed, having their interior surfaces lined with polished plates of ebonite, and the material appeared throughout, so far as one could judge by inspection, to be of uniformly good quality.

As the practical conclusion from these observations, I would call attention to the fact that there are different qualities of ebonite apparatus in the market, and it is, therefore, important to look for the guarantee of quality which the name or stamp of the maker affords, and by all means into decline accepting articles like those which first came to my hands, in regard to which it is almost needless to add that there was no trade mark or means of identification.—I am, dear sir, yours faithfully,

JOHN SPILLER.

Woolwich, August 24th, 1863.

[The bath to which we referred as proving satisfactory in our hands, was manufactured by Messrs. Silver and Co. If we are rightly informed, the manufacture of "Ebonite" is protected by a patent, and any imitation under the name of "ebonite" would be an infringement.—Ed.]

A CASE OF NEED.

MY DEAR SIR,—Having just returned from a small watering place where I found the widow of a photographer of some repute struggling hard for a livelihood with a *wretched* lens and camera, may I ask the favour of your bringing her case before our photographic brethren, professional and amateur, and soliciting their aid towards procuring for this worthy and industrious sister a suitable apparatus wherewith to support herself and *three* orphan children. At her husband's death, being then ignorant of the art, all her lenses, &c., were disposed of by a relative. She has since been taught, and only now fails to attain her object from not having a lens, &c., fit for the purpose. I am sure, sir, you will kindly consent to receive subscriptions, and the smallest donations will be thankfully received.—I remain, my dear sir, your constant reader, AN AMATEUR PHOTOGRAPHER.

Photographic Notes and Queries.

MOISTURE AND ACTINISM.

DEAR SIR,—I, with several of my photographic friends and not a few of your correspondents, have lately been complaining sadly about the want of intensity in their negatives, notwithstanding the recent and present summer light.

I should inform you, sir, that the floor of my glass room is paved with red tiles, and therefore you will readily understand that with a southern aspect the heat is usually very excessive and the atmosphere correspondingly dry. To alleviate the heat, the other morning, I poured through the "rose" of a watering pot a large quantity of water on the tiles, and although in a few moments the water was absorbed, the evaporation continued for several hours. To my gratification on taking a negative it not only came up dense and standing out from the glass, but required no after intensifying from the iron developer. I do not absolutely assert that the dampness in the air of the room had anything to do with the improvement, but on trying the same thing this morning I met with the same pleasing result.—I am, sir, yours very truly, NOEL E. FITCH.

[The fact stated by Mr. Fitch is curious, and as we know him to be a most careful and skilful photographer, his experiments and opinions possess considerable weight.—Ed.]

NEW TRANSPARENT MEDIUM ON TO WHICH NEGATIVES MAY BE TRANSFERRED. NEW PRESERVATIVE.

SIR,—I have not seen any reference to a substance which seems peculiarly adapted as a preservative in the dry plate process, also as a transparent sheet upon which to place negatives instead of glass plates that are so liable to get scratched and broken. I refer to a mixture of gelatine and glycerine; the latter readily dissolves glue or gelatine by the aid of heat in an ordinary glue pot, forming a mixture which, when spread on glass and allowed to set, may be taken up as a beautifully transparent sheet, exceedingly flexible; or the hot solution may be poured on the unvarnished glass negative, and, when set, the impression becomes attached to the gelatine, and is then more convenient for all printing purposes, and the density of the negative is not impaired by varnishing as on glass plates. Such sheets, containing negative images, are most convenient for photolithographic purposes and for photographic printing surfaces generally, as, from its flexible nature, it adapts itself to the sensitive surface of either stone or plate in the closest contact.

Query—If a very dilute solution of the above be applied to a collodion plate sensitized, I feel certain it would prove a valuable preservative, it will certainly make a better combination than gum and honey. It retains its *viscidit*y for years.—Your obedient servant, JOSEPH LEWIS.

Talk in the Studio.

MONUMENT TO BISHOP HOOPER.—We have received from Mr. H. T. Bowers a very fine photograph on a 15×12 plate of a monument which has just been erected at Gloucester, by public subscription, to Bishop Hooper, the Protestant martyr. It is a noble structure, placed in the churchyard of St. Mary de Load, an ancient and curious church built partly upon the foundation of the first Christian church which was built of stone in this country. The photograph is very perfect indeed.

NOVEL USE OF CARD PICTURES.—It is stated that, at a recent great ball, given by the Empress Eugenie, each guest was requested to bring a card picture of the costume in which he appeared at the ball. The portraits were then collected, and placed in an album for the boudoir of the Empress.

PHOTO-LITHOGRAPHY.—The *Times* gives the following from *Calignani's Messenger*, a few days ago, both papers evidently fancying the matter a novelty:—"A curious communication was sent in last week to the Academy of Sciences, by M. Morvan, in which he describes a method of his for obtaining direct photographic impressions upon stone, and which he can afterwards print off. He first gives the stone a coating, applied in the dark, of a varnish composed of albumen and bichromate of ammonia. Upon this he lays the right side of the image to be reproduced, whether it be on glass, canvas, or paper, provided it be somewhat transparent. This done, he exposes the whole to the action of light for a space of time varying between thirty seconds and three minutes, if in the sun, and between ten and twenty-five minutes, if in the shade. He then takes off the original image, and washes his stone, first with soap and water, and then with pure water only, and immediately after inks it with the usual inking roller. The image is already fixed, for it begins to show itself in black on a white ground. He now applies gum-water, lets the stone dry, which is done in a few minutes, and the operation is complete; copies may at once be struck off by the common lithographic process. The process may be explained thus:—The varnish has been fixed and rendered insoluble by the action of light wherever it could penetrate; but, on the contrary, all the parts of the varnish protected by the dark portions of the image still retain their solubility, and are, therefore, still liable to be acted upon by the soda and acid contained in the soap, of which they, moreover, retain a part of the substance. Hence the action produced on the stone is a combination of etching and lithography. The advantages of the process may be briefly summed up as follow:—Simplicity and rapidity in the operation, exactness in reproducing the design, no need of negative impressions on glass or paper, the positive original comes out positive, the original design or model is not spoiled during the process, and the cost is trifling, owing to the cheapness of the substances. [The process here, not very clearly stated, does not appear to differ much, in principle or application, from Cutting and Bradford's process, patented some years ago.—Ed.]

To Correspondents.

HENRY THOMPSON.—The best cement we know for joining glass is marine glue; we have not found it injure the nitrate of silver solution. 2. Chemically, the print sent is very good; but there is room for improvement in the posing.

AN AMATEUR.—The sensitive plate should remain moist and ready for use a few minutes at all seasons, unless something be wrong. A horny repellent collodion is more apt to dry quickly than a somewhat porous and absorbent film. It has been recommended to place a piece of wet blotting-paper behind the plate, which by keeping it cool and filling the dark slide with moisture tends to prevent the plate drying. A plate may dry in daylight after fixing without any detriment to its subsequent intensification. We intensified a plate successfully a day or two ago, which was taken upwards of two years ago, and has stood in the light a great part of that time.

IGNORAMUS.—You may develop any collodion with iron, whether especially manufactured for iron development or not, and you will generally gain in rapidity by doing so. 2. You will find a good formula for collodion in our *ALMANAC*, which will answer your purpose and for most of the dry processes. 3. We are uncertain as to the suitability of the collodions you name; they will probably require the addition of a little more bromide. 4. You may use the ordinary sweet wort from a brewery for the malt process; it should be filtered. 5. It is quite legal to make acetic acid by the distillation of acetate of soda or potash with sulphuric acid. It is also legal to distil ether; and to redistil alcohol, but not to manufacture it without paying duty. 6. Citric acid is made by adding chalk to lemon or lime juice, which forms insoluble citrate of lime. This is decomposed by adding dilute sulphuric acid, and on evaporation crystals of citric acid are obtained. 7. Citric acid does not spoil by keeping in crystals. 8. Yes. 9. A candle will do no harm in the dark room unless its flame be brought too near an open bottle of collodion or ether, or its light too near an excited plate. 10. You might recover your silver as a carbonate and then produce nitrate

direct if you used distilled water always for washing; but if you use common water, some of the silver will be thrown down as a chloride by the chlorides in the water. A great deal of the silver in waste developing solutions is gradually thrown down as a metallic powder.

YOUNG ENGLAND.—An ordinary spirit varnish is sometimes used to varnish card pictures, but we do not consider them improved by the operation. 2. You may make chloride of gold from a gilder's waste by simply dissolving it in nitro-muriatic acid, as we have often described.

ST. DENNIS.—We believe that Marion and Co., of Soho Square, manufacture albums, and also Mr. Bourquin, of Newman Street, Oxford Street.

AMATEUR.—The defect in your tannin plates appears to be fog. Use a weaker and more acid developer; or add a little acid to your nitrate bath. We do not consider the printing through of the sky a defect if the picture be good in other respects. With a view-lens of $\frac{1}{4}$ -inch focus and half-inch stop, an exposure of two minutes in a bright light is longer than necessary with an ordinarily good tannin plate. 2. With calotype paper, an exposure of five or six minutes would probably be sufficient in a bright light, with lens of 12 inches focus and $\frac{1}{8}$ ths stop. 3. So far as we can judge, without absolute comparison, we should say that, in point of sensitiveness, ordinary tannin plates and calotype paper were very similar.

W. G.—We have only tried one out of the three you name, the second, and it was very good.

LIME TONING.—A correspondent, who, a few weeks ago, lamentably failed with a lime bath we had described, encloses us a couple of very fine prints indeed, stating that he tried it again when it had stood a fortnight, and that all now goes well. It only required age.

A.—We think that the tannin process exceeds in simplicity and certainty the Fothergill process.

A.—If a portrait painter who advertised in our pages, June 26th, under the signature "A," will call at our office, he will find another communication awaiting him.

W. BASSANO.—We understand our correspondent to mean that he used a bath of the strength mentioned, daily, and not the same identical solution. If the latter were meant, no specific deduction could be drawn from the fact, except as to the strength, without knowing the quantity of solution. A weak or a strong bath will become impoverished, and requiring strengthening and renewing, but the economy of the weak bath, if satisfactorily established, would consist in leaving much less free silver to be removed by washing. We have printed with very weak baths successfully, but we have an impression that when the tendency to mealiness exists, they promote it, and can only be used with very good vigorous negatives. 2. We are not aware that any one has done anything with gum and formic acid as a preservative. We shall be glad to hear of your results. 3. India-rubber dissolved in kerosene, or other solvent, possesses the advantage over albumen as a preliminary coating, that there is no danger to the bath from its use, which is not always the case where albumen is used.

CHALK.—We are glad that our suggestion has helped you. Had we seen a plate we could have told you the cause of the defect at once. Possibly the fact that over-iodizing will produce those irregular fringe-like stains is not sufficiently explained in many works on photography.

PERPLEXITY.—We will take an early opportunity of trying the paper and reporting.

JOHN VANHEM.—We will make some inquiry into the matter. It is quite possible the matter is susceptible of some explanation. We have an impression that the manufacturer has been very ill.

SHAW AND SONS.—The group and general artistic arrangement are pretty good, there is a little want of sharpness, possibly from movement.

G. L.—Carbonate of lime is slightly soluble, in most common waters, as you may easily prove by agitating the water with a little chalk, and then filtering the water until it is quite clear and bright. Now add a little oxalic acid, which will cause turbidity, and finally a slight precipitate of insoluble oxalate of lime.

Several Correspondents in our next.

ON THE MANAGEMENT OF THE NITRATE BATH.

THERE is no preparation used by a photographer of more vital importance than the nitrate of silver bath, and yet none in regard to the condition of which he possesses so little certainty. By care he can secure collodion of constant quality; or at the worst he can be certain that the stock in use for a given period, say a day or a week, or months, continues unchanged. In his developing solution he can secure just what conditions he may please, unvarying in all respects if he desire. But in regard to the nitrate bath, none of these things are possible: it is continually changing; it is not the same bath for two consecutive plates. In using the collodion and developer a definite portion of each is consumed, and what remains behind continues of the same quality. The nitrate bath is continually being deprived of some of its elements and receiving an accession of others; there is a constant interchange of particles. It is composed, to begin with, of water, nitric acid, silver, iodine, and perhaps a trace of bromine. On the immersion of every plate it is deprived of a portion of its water and silver in uncertain quantities. It is supplied in place of the silver with some other base, or a mixture of bases, it may be cadmium, potassium, ammonium, lithium, magnesium, calcium, zinc, and occasionally a trace of iron. It receives besides continued accessions of ether and alcohol and probably traces of other organic matter. It also probably continually gains accession of some traces of iodine and bromine, and there is a gradual accumulation of iodo-nitrate of silver. Besides the decompositions and recompositions which are intended to take place, and which are anticipated in the order of things, there are others not always intended which are uncertain and beyond control, such as arise from the liberation of nitric acid and oxygen by free iodine in the collodion, and from the reactions between ether and alcohol and free acid. There may be the train of complications arising from the addition of acetates. There may be occasionally other decompositions arising from unknown empirical additions to increase the sensitiveness or density of collodion, or the use of impure methylic solvents in its manufacture. When all these considerations are remembered, and that the changes produced never remain for two plates the same, it is scarcely surprising that nitrate baths occasionally "get out of order."

It happens fortunately for photography and photographers that a nitrate bath of originally sound and healthy constitution, is very hardy. If made originally from pure materials, and worked with ordinary care and moderately pure collodion, it will continue parting with much it originally possessed, and receiving much foreign addition to its constitution without striking work or being attacked with sickness. Nevertheless, of late there have been frequent complaints from good photographers, amateur and professional, of the rapidity with which their baths get out of order and

refuse to give satisfactory results. Various causes are alleged. Some attribute it to the use of bromides in the collodion; others, to the uses of methylated spirits as solvents of pyroxyline; others to the use of ordinary alcohol distilled from potato, malt, &c., and containing essential oils; others, to organic additions to the collodion; others, to impure and unsuitable iodizing salts; others, to the prevalence of adulterated or impure nitrate of silver.

All these causes may, occasionally, be chargeable, but there is another, which, also, possibly has more influence than is recognized. We allude to the enormous amount of work the nitrate bath frequently gets, to what it used to do a few years ago. Since the introduction of card-portraits, we imagine that in many portrait establishments ten-fold more negatives are produced now than were a few years ago; and the nitrate bath gets a proportionate increase of work in the time.

Without adverting further at present to these causes which are largely beyond the control of the photographer, it becomes an important question with him, therefore, to consider, first, how to best keep his bath in order so as to secure constant conditions, and next how to rectify it when out of order. We shall devote a few lines to each of these subjects.

How to Make and Keep the Bath in order.—Make the bath of a strength of thirty grains to the ounce for summer, and thirty-five grains, or forty, to the ounce for winter use. Iodize it, by leaving a large coated plate in for a few hours. If it work foggy neutralize with freshly precipitated oxide of silver, or carbonate of soda, and sun for a few hours. Then filter and try again, working it as nearly neutral as possible, adding, if acid be necessary, the smallest trace of nitric acid. We will now suppose the bath is in good working order, and the object is to keep it so, or what is equivalent to secure the greatest possible constancy of good conditions.

We now ask the careful attention of our readers for a moment. We have already said that the nitrate bath is beginning to change its constitution from the moment it is brought into use. No care can prevent the accumulation of foreign matter in the bath, but the greater portion of this would be comparatively inert in determining the character of the sensitive film of iodide and bromide of silver, if we could remove it from the free nitrate on and in the film which is reduced in developing. The affinities exist between iodine and bromine and the silver in the solution, and these elements will combine, forming iodide and bromide of silver, regardless of the foreign matter which may be present. It is true that foreign matter present may become to some extent entangled in the film with these elements as they combine, the more so if the idea be accepted of the formation of sensitive double salts of iodide and nitrate of silver and bromide and nitrate of silver, but it is to the presence of the foreign matter in the free nitrate on the plate that irregular reduction, causing stains, fogs, pinholes, &c., &c., is chiefly due.

How are these impurities in the free nitrate to be got rid

of, then? Very simply: by the use of two baths. Most professional photographers in large practice have two or three baths going, and some require a new one every two or three days, not because the old one is exhausted, but because it is saturated with foreign matter, that it does not work well. Proceed as follows:—Make a new bath as usual, and get it into perfect order; do not excite the plates in it, but in the old one which is supposed to be done. When the plate is withdrawn from this, covered, it may be, with greasy lines, from the accumulation of ether and alcohol, or covered with a sandy looking deposit, the sure forerunner of pin-holes, &c., instead of putting it into the dark slide, put it into the new bath for a few seconds, moving it up and down once or twice. Now remove it to the dark slide—the greasy lines from ether and alcohol are gone—it looks perfectly smooth and even—the sandy deposit is removed, and all loose particles which have accumulated in the first bath from long use are washed off—the contaminated free nitrate which saturated the film is almost entirely replaced by a new solution. When the developer is applied it flows evenly over the plate, does not readily decompose, and, whilst it develops the image, it reduces pure nitrate of silver, and thus avoids the fog, streaks, pin-holes, &c., which are the common result of free nitrate containing organic and other contaminations. The negative consequently possesses all the delicacy, cleanness, and richness of colour which are the general result of a new pure bath.

Besides the good results, there is a great saving effected. The new bath receives such slight additions of foreign matter that it serves as a second bath a very long time; whilst the first bath may be used much longer than it could possibly be under other circumstances. When the first begins to be exhausted and useless, the second bath may be put in its place, and a new one made for the second immersion.

Some years ago, when glass positives were in vogue, we tried a similar plan, but with a slight modification. The second bath contained only ten grains to the ounce, the object being to avoid the rapid precipitate of a large amount of surface silver which had a tendency to bury the half-tones and give a coarse image. With the dilute second bath we had development more under control, and secured great delicacy and fine modelling. Our attention was recently called to the advantages of the second bath by a well-known metropolitan portraitist. He had been somewhat troubled by the frequent necessity for new baths. Every week three ounces of nitrate of silver were necessary for replenishing the old bath or making a new one, and a large accumulation of bottles of discarded nitrate solution began to fill the dark-room. The ether, alcohol, &c., accumulated and spoiled the solution much more rapidly than it was used up, and time was too precious to permit of evaporating, sunning, &c. The plan of using two baths, as we have described, was therefore tried, and found to answer admirably; the increased comfort, economy, and excellence of results, being out of all comparison greater than before. The trouble was found to be comparatively trifling. A plate was coated and excited in the old bath; then removed and placed on a piece of blotting paper to drain. Whilst it was doing this, another plate was put in the old bath, and then the first was sufficiently drained for immersion in the second bath, where it was allowed to remain about half a minute before placing in the dark slide.

Replenishing the Bath.—The common method of replenishing the nitrate bath is by the addition of fresh solution of the proper strength, or of a stronger solution where there is reason to suppose that the strength of the used bath has become impoverished. From some scarcely explained cause it is often found that the first result of such replenishment is not always improvement. It not unfrequently happens that a tendency to fog and streaks is the first result. These troubles may however be avoided by adopting another method of proceeding. Instead of making new solution, first take the proportion of water and add to the old solu-

tion. This will throw down some portion of the accumulated iodide which was dissolved in the old solution. Now filter, and add the crystals of nitrate of silver necessary to make up the proper strength. By adopting this method it will often be found that the bath is much improved, and the troubles attendant on the old method avoided.

We must defer our remarks on the correction of baths out of order until our next.

REPRODUCTION AND COPYRIGHT.

ONE of the most interesting features which struck us as distinguishing the French Photographic Exhibition, was the magnificent display of photographs from modern copyright paintings, rivalling engravings in all points in regard to which engraving is supposed to possess especial advantages, and decidedly surpassing it in others. In faithful translation of colour, in chiaroscuro, and in delicacy, vigour, and beauty, many of them—we are especially speaking of those of Bingham—leave nothing to be desired; whilst in accurate rendering of exact drawing, and even the very touch and handling of the artist, and in cheapness, they possess decided advantages over engraving.

In this country the experiment of producing photographs from modern paintings has not been tried to any considerable extent. This has been doubtless due to two causes. In the first place, the absence, until last session, of any means of securing a copyright in such productions; and in the second place, little demand existing for such work, there are not many good photographers who have devoted attention to the especial production of such works, so that an impression largely prevails that it is impossible by means of photography to translate into satisfactory monochrome the varied bright hues of modern painting. This first reason has ceased to exist, the new act affording effectual protection both to the painting and the photograph. In regard to the second the demand only needs to arise in order to bring forth capable men. Mr. Thurston Thompson's photographs of Turner's paintings, and Mr. Annan's copies of the prize paintings in the Glasgow Art Union, are sufficient evidence of the existence of capability in this direction, and we are satisfied that there are many more if the demand arose for their services. Mr. Gambart, in his recent pamphlet on copyright, suggests a third reason, the low estimate into which photographic reproductions have fallen having been chiefly confined to the hands of pirates. He says:—

Want of justice to the art of engraving, and its being delivered as a prey to unprincipled photographers, has been more destructive to photography than can be generally understood. This course has not destroyed a trade which existed before, but prevented one of great promise from being developed. Photographic copies of engravings, having got possession of the market, are produced by only the lowest practitioners. No photographer of standing or ability will join in such a course. The sale of copies of English engravings is only carried on by hawkers or shopkeepers of broken fortunes, and their competition being unrestrained by want of capital, such copies, originally sold at from 1s. to 6s. each, are now produced at the lowest possible price—one party actually supplying the trade with small photographic copies of my engraving from "The Light of the World" at three-halfpence a dozen, so that the vendors can make but a slender return out of their nefarious practices. But, the low prices thus established ruling the trade, publishers of photographs in which there would be copyright, and consequently capital invested, have no chance—the necessity of charging a corresponding high price limiting their sales to the lowest ebb. And yet what a fine future photographers have before them! Already in France, under an efficient copyright law, the photographer competes successfully with the engraver. Messrs. Bingham are reproducing Meissonnier's pictures in photography with the greatest success. Gérôme's "Gladiators" and "Death of Cæsar," and many other fine works are published in photography also, and large sums have been paid for copyright to the artists by the publishers of these photographic reproductions.

What is the case in England? Where are the pictures reproduced by English publishers of photographs? What sums have painters received from photographers? I fear the answer is, None! The sole cause of the unprofitableness of photography, as a medium for reproduction in England, is to be found in the trade in photographic transcripts being in the hands of pirates. I do not speak on mere speculation and without proof: I have given photography a trial. I published, in photography, one of Mdlle. Rosa Bonheur's finest pictures, "The Shetland Ponies," and although the picture was most creditably reproduced by Mr. Thurston Thompson, I have, after six months of publication, not sold one hundred copies; the reason is obvious, printsellers will not buy my photographs at the price I am obliged to charge (not having stolen the copyright, but having paid for it a fair price to Mdlle Rosa Bonheur as part of the purchase of the picture), in order to recompense myself by spreading my outlay over a fair edition, besides requiring an additional remuneration for my industry. Of course my experience is of a dead failure and a losing speculation; whereas, if the photographic trade was not affected by the disease of piracy, not only would my publication be successful, but publishers of photographs would compete with publishers of engravings in the purchase of copyrights, and, by further enhancing the value of artistic talent, encourage artists to greater efforts in view of the prizes held out to successful competitors in a race where fortune follows fame.

If Mr. Gambart's view of the case be a correct one, it is unfortunate for the public and for photographers. A copyright law, efficient so far as this question is concerned, is now in existence, and consideration of want of protection need now operate to prevent photography, in many cases, taking the place of engraving for the reproduction and extensive distribution of the works of modern painters. In France it is not simply paintings which are not worth engraving which are so reproduced; some of the first artists of the day thus deal with their best paintings. We saw in Mr. Bingham's studio, waiting for reproduction, one of Meissonnier's paintings not exceeding twenty-four inches by eighteen in size, which had been sold for two thousand guineas; and we saw various copies of other first-class paintings which had just been completed. What are the precise copyright arrangements in France, or whether they possess any advantages over the copyright law recently adopted in this country, we cannot say; but we cannot see any valid reason whatever why this system of reproducing copyright paintings by photography for publication should not be adopted in this country. The success of last year's experiment has induced the Glasgow Art Union to repeat it, and photographs of original paintings are again to take the place of engravings in the general distribution, the work being entrusted to Mr. Annan, who so successfully produced last year's pictures.

The great success of Mr. Bingham in this department of the art has led to the conjecture amongst some persons that he possesses some secret upon which success depends. An eminent Parisian photographic authority expressed to us his conviction that this was the case, remarking that he had never published his process, and that, as his productions so far surpassed all others of the same class, it was probable their excellence depended on superior method. In a subsequent conversation with Mr. Bingham, he informed us that his only secret consisted in the use of judgment and careful manipulation. He used a collodion containing one part of a bromide to three of an iodide, about four grains and a half of the latter and one and a half of the former, the base generally being cadmium. The pyroxyline was made by a formula very nearly resembling that we publish in our YEAR BOOK, with the exception that the nitric acid contains a portion of nitrous acid. An iron development was used, generally somewhat strong, but varying with circumstances. Mr. Bingham has so long used a bromo-iodized collodion and iron development, and so thoroughly proved their advantages in trying work, that he had been much surprised and amused to see the question of their value recently raised in the English journals. The question, in his practice, did not admit of a doubt.

Mr. Bingham's studio is one of the noblest in dimensions,

and the most convenient and comfortable, we have seen. Its length is between thirty and forty feet, its height is not much less, we should think, than thirty feet. It has a ridge roof with a very steep pitch, the ridge running crosswise of the room. The sitter can be placed at either end, the half of the roof under which he is placed being covered up with blinds and the top light from the other side reaching him at an angle of about forty-five degrees. Each side is fitted with glass and possesses double moveable sashes, one of which is glazed with ground glass for cutting off direct light when necessary. A gallery or balcony runs round outside the studio. The camera is placed in a moveable dark room which prevents diffused light entering the camera. The arrangements throughout were amongst the most perfect we have seen.

PHOTOGRAPHS IN PRINTING INK.

In some interesting remarks by Mr. Sutton, in the last *Photographic Notes*, on Mr. Pouncy's new process, he refers to a very important mode of using it. He says:—

"If it is required to exhibit a carbon print upon plate paper, so that it may have exactly the appearance of an engraving, with all the peculiar merits and qualities of a photograph—and this is certainly a very desirable method of printing—then the print must be transferred from the tracing paper to the plate paper. This is very easily done by a peculiar process, which only occupies a minute or two, and requires a lithographic press. The tracing paper comes off as clean as it was at first, and the ink picture is transferred to the white paper, non-reversed."

If this can be effected satisfactorily, it will be, we apprehend, one of the most important applications of the process. We have not seen a specimen treated in this way; but shall look with interest for results in this direction. Mr. Sutton further adds:—

"In the same way, the carbon print can be transferred to a stone or zinc plate, and is then ready to be put into the hands of the lithographic printer. The mode of transferring is, however, quite new, and the stone, instead of being dry and hot, as in the usual process, is damp when the transfer is laid upon it. This is another of the novelties included in Mr. Pouncy's patent.

"Let us now recall to mind what has been done.

"1st. A positive print has been taken in printing ink upon transparent paper, which may either be viewed as a transparency, or exhibited mounted upon cardboard.

"2nd. A positive print in printing ink has been taken upon white paper.

"3rd. A positive print in printing ink has been transferred to a lithographic stone,—the impression, which is already in ink, being perfect in all the gradations of tone.

"In all previous attempts at Photo-Lithography the image upon the stone has been perfect in half-tone, but it has not been obtained in ink, only in bichromate of potash, or asphaltum; and the difficulty has been to preserve the half-tone when the ink is applied. Mr. Pouncy has overcome that difficulty, and by his new process has obtained a perfect image in fatty ink upon the stone. It is this which constitutes the solution of the grand difficulty in Photo-Lithography. It only remains for the printer to etch the stone slightly, and produce the grain, which is an essential characteristic of a lithograph, and then print off impressions in the press."

PHOTOGRAPHIC CHEMICALS:

THEIR MANUFACTURE, ADULTERATION, AND ANALYSIS.

THE metal *arsenic* next claims our attention. Many compounds of this element are of value in photography, and are in other respects of considerable importance. What is commonly known as arsenic is not the metal properly so

called, but its teroxide, arsenious acid, a white powder. Arsenic itself is a true metal in physical appearance, being tin-white inclining to steel-grey, and possesses a bright metallic lustre. It has one property which distinguishes it from all other metals; it will not fuse. When heated in a glass tube it begins to volatilize at a dull red heat without previously fusing, subliming and condensing in the form of a coherent crystalline mass, not very hard, but very brittle. If an attempt be made to fuse it by heating it in a sealed glass tube, the tube bursts, but no fusion takes place.

By far the most important compound formed by this metal is the teroxide, arsenious acid, above mentioned. This is generally formed when metallic arsenic is heated in the air till it volatilizes. It then burns with a reddish smoke, or when more strongly heated, with a pale blue flame, having an odour of garlic. When the metal is wetted with water and exposed to the air it likewise becomes superficially coated with arsenious acid. When the metal is finely powdered and then moistened with water, it oxidizes so rapidly as to become heated, and in one instance a large quantity (8 lbs.) actually took fire spontaneously. When arsenic is heated with oil of vitrol or dilute nitric acid, arsenious acid is formed. On the large scale arsenious acid is prepared by roasting arseniferous minerals in a furnace from which the fumes are conveyed into a horizontal condensing chamber called the *poison-trap*, or into a building called the *poison-tower*, containing a number of chambers placed one above the other. The crude arsenious acid obtained in this manner is purified by resublimation, having been previously mixed with a small quantity of crude potash to retain the sulphur. Arsenious acid occurs in two varieties, crystalline and amorphous. The former is the kind usually met with in commerce. The amorphous variety is obtained by heating the common variety suddenly or under increased pressure. It then forms a transparent, and colourless glass, which, upon keeping for a few months, becomes white and opaque. During the passage of this amorphous acid to the crystalline state a very remarkable phenomenon of the emission of light is observed. When from one to one and a half parts of transparent arsenic glass are dissolved by half an hour's boiling in a mixture of six parts fuming hydrochloric acid and two parts of water, and the solution left to cool as slowly as possible, the arsenious acid crystallizes in transparent octohedrons, and the formation of each crystal is accompanied by a spark; on agitation, which gives rise to the formation of many new crystals, a corresponding number of sparks is produced. If from four to six parts of arsenic glass are dissolved in the above mentioned mixture, the light produced by the crystallization is sufficient to illuminate a dark room. As long as the deposition of crystals goes on so long is light perceived on agitating the liquid; and this appearance may be visible on the second, and even, though very faintly, on the third evening. If the liquid be then boiled so as to dissolve the remaining portion of the nitrous acid, crystallization again takes place, accompanied by emission of light, though not so bright as before. If the liquid be rapidly cooled, the acid separates in the pulverulent state, and little or no light is emitted. This production of light during crystallization is not uncommon, but we are not aware of any compound which emits it in such abundance as arsenious acid. Much remains to be done by physicists in this branch of science, and it would be well worth some experimentalist turning his attention to this almost neglected field. Even as the subject now stands, we see that a dark room can be illuminated by the crystalline light of one of the cheapest chemicals, and if experiments were specially instituted in the endeavour to exalt or intensify this action we can well imagine that some most valuable facts would be elicited.

It is almost superfluous to say that arsenious acid is one of the most violent among the acrid poisons. It has a rough taste, slightly metallic and afterwards sweetish.

The solubility of arsenious acid in water is variously stated by different authorities, varying, indeed, as much as

from one part in six of water to one in sixty; probably one in forty is about the true proportion. Its aqueous solution is transparent and colourless, and reddens litmus slightly. Arsenious acid dissolves easily in an aqueous solution of potash, forming an oily, alkaline liquid, which, upon evaporation, leaves a gummy mass. It is very difficult to obtain a definite crystallizable arsenite of potash.

When arsenious acid is heated with an oxidizing agent, strong nitric acid for instance, it takes up two additional equivalents of oxygen, and from As_2O_3 becomes As_2O_5 arsenic acid. This acid has recently become of some considerable commercial importance, owing to the fact that it is the best and cheapest oxidizing agent which can be used for the conversion of aniline into rosaniline and its salts (commonly known as magenta). Commercially it is prepared by dissolving either metallic arsenic, or arsenious acid in strong nitric acid, to which a small quantity of hydrochloric acid has been added. The liquid is evaporated to dryness and, if it be desired to get rid of all the water, the residue is heated to redness. Arsenic acid, after fusion, is colourless, transparent, and glassy; at a low red heat it melts; it reddens litmus strongly and is excessively poisonous. At first it is almost tasteless, but afterwards it tastes very sharp and acid. Arsenic acid deliquesces in the air; it dissolves slowly in six parts of cold water, more quickly in two parts of hot water. On evaporating the solution a syrupy substance is obtained from which small crystals of arsenic acid are deposited. In aqueous solution, arsenic acid is colourless.

This substance has recently been the subject of considerable discussion in a court of law, on which occasion, as is usual when scientific points have to be argued before a jury, the chemists were ranged about equally on each side. A patent was taken out for the employment of *dry* arsenic acid in the manufacture of magenta. It was found by other parties (defendants in the action,) that *anhydrous* arsenic acid would not answer the purpose, but that a certain quantity of water was necessary for the decomposition. Just so, said the plaintiffs, we admit that a little water must be present, but that is understood when we speak of *dry* acid; we obviously mean the common, air-dry substance, looking dry to the eye and feeling dry to the touch, and this common dry acid contains the necessary amount of water. The trial resolved itself into a discussion as to the relative values of *dry* and *anhydrous*. The latter term means absolutely and positively free from every trace of water, and if *dry* meant the same thing, the patent was invalid; whereas if *dry* were held to mean such a state as would look and feel *dry* to an ordinary observer, the patent was good. Ultimately it was decided that the latter supposition was correct, and in this view of the case we most certainly agree. *Anhydrous* is not a term capable of being employed in ordinary life. It is strictly a scientific word, and in chemical treatises is always used in its true exact sense. Powders, apparently the driest, are exposed to a high temperature in a current of hot air, in order to render them perfectly anhydrous; we talk of getting a gas anhydrous when there may be only 1-10000ths of its weight of water present to begin with. Moreover, the term *anhydrous* is used indiscriminately to imply freedom from water, whether in the form of vapour, liquid, or ice, but the term *dry* is exclusively used to denote freedom from *liquid* water. Thus we constantly speak of *dry* bread (containing 30 per cent. of water), *dry* steam, *dry* snow, and *dry* ice; but to speak of *anhydrous* steam or *anhydrous* ice would be an absurdity.

AN ATTEMPT TO SECURE CERTAINTY IN GOLD TONING.

BY A PHOTOGRAPHER'S ASSISTANT.

The manifold difficulties which beset the labours of the photographer, must of themselves be sufficient to convince the most prejudicial observer that, however strong the claims

photography may have in demanding its recognition as a fine art, it cannot, as yet, legitimately take its place in the list of perfected sciences; for, strictly speaking, the term science can only be applied where principles are reduced to a system, the governing laws of which must be so clearly defined that the student may regard them as the friendly finger-post to guide him in his researches.

Accepting as a criterion the discrepancies that occur in the experience of those who have been experimenting in lime toning, the correctness of the foregoing remarks will be admitted; for, whilst the few are successful, the many still despairingly cry, "Who will deliver us from the present evil?" Meal, meal, every formula we try; every scheme we adopt prove failures. Oh for the universal specific to rid us of this direful disease! To seek a remedy without an attempt to discover the true cause, by the practice of observation, is to place us on a level with empirics in general, whose success is the results of chance, the presiding goddess of which is seldom lavish in the distribution of her capriciously offered favours.

Touching the subject before us, the first question suggested for consideration, is the nature of the disease. We are all but too familiar with its appearance: are we so familiar with its nature? I trow not, or mealiness could long ere this have been banished from our printing rooms.

Long and patiently repeated observations have strengthened and, I may venture to add, confirmed the opinion expressed on this subject in a former paper, viz., that what we term mealiness is, in reality, the removal of the reduced silver from the more thinly coated portions of the paper surface. However carefully the paper is manufactured, there will be found minute threads on its surface, which, after pressure, stand out in grain-like relief, receiving the thinnest coating of albumen, and, consequently, the smallest proportion of silver, which, when acted upon by the toning solution, readily dissolves out, leaving the whitened surface in speck-like comparison with the adjacent perfectly toned, because more stable parts. Hence, what we term bleaching is the results of bleaching or the action of reduction on an uneven surface; and the many causes which produce the evil, if minutely examined, will be found to act as accelerators to the above described influence. If a perfectly smooth surface could be attained to receive the coating of albumen, mealiness could never make its unwelcome appearance, over-bleaching would produce flat prints, nothing more; and here I would suggest, that a portion of the unprofitable labour employed on the surface of paper after albumenizing, if applied previous to its receiving the coating of albumen, it would go far to remedy the evil. But accepting and endeavouring to make the best of things as we find them, we now enter on a consideration of the means at our disposal that will enable us to hold in check the bleaching power of our toning solutions. This power has been sought after in various directions, and the conclusion arrived at is, that until we can find a true theory for explaining the chemistry of toning action, the power to govern its movements will be denied us. I cannot admit the soundness of this mode of reasoning, for although the intricate changes which take place during the process of toning, may not be understood, we are not denied the power of reducing its general principles to something like order, and until this is done we shall even be floundering in a chaos of dark insoluble perplexities. As an illustration to my meaning, I may be permitted to refer to the electrician. He knows absolutely nothing respecting the constitution of the subtle fluid with which he has to deal, swift as the lightning's flash it moves. Yet a knowledge of the laws by which it is governed enables the individual described to hold it under perfect control. What are the bleaching agents employed in the process of alkaline toning? We answer, chlorine in contact with gold: and in the lime bath, also chlorine in combination with lime; but, this agent, until separated from its base by another power, remains comparatively inert. The decomposing influence here employed is the free acid introduced with the gold. Without venturing

an explanation as to the manner in which this is effected, we would just say, hold in check the cause, and you have at command the effects; remove the acid and you destroy the bleaching power; yes, and the same time stop toning action also, for the one must accompany the other. Non-bleaching in most cases means non-toning; proof of this may be found in the fact that a toning compound of whatever description may have its action destroyed by saturating the solution with carbonate of lime, or by the addition of any alkaline agent in sufficient quantity to destroy every trace of free acid. Whether the bath be old or new, strong or weak, the same result will follow; then, with this knowledge, our path lies straight before us. Reduce the bleaching power to the lowest point that can be admitted without destroying toning action, and this may be accomplished by an observance of the rules laid down in my last brief and hurried communication. By the application of heat remove a portion of chlorine from the gold, partially neutralize the free acid with soda carb., the carbonate of lime introduced with the chloride will remove as much as required of the remainder; if bleaching is too strong, add more soda; if weak, and toning is slow and staid, reduce the quantity of soda. Keep on experimenting until you have secured the necessary conditions. If this advice is intelligently followed by your readers, we shall have less complaints of failures in toning trials; and, in conclusion, I would urge on those desponding ones to persevere, for those who prescribe remedies acquire their knowledge by passing through the same ordeal of difficulties.

In conclusion I would apologise for the lengthened remarks which were suggested by your ably-written article on lime toning, and add that, when time will permit, I intend entering on the causes of success and failures in general, where photographic printing is concerned.

[Our contributor being very anxious to assist his photographic brethren in their toning troubles, has undertaken to test any sample of paper with which our readers, using his modified formula, may fail in getting good results. Address to him under cover to us.—Ed.]

PHOTERGIMETRY.

BY SIG. GARNERI, OF TURIN.

The photergimeter is an instrument intended to measure with precision the degree of intensity of the chemical action of light. It is constructed as follows:—Some positive paper is prepared upon concentrated baths of definite strength, the one, a solution of sal ammoniac at 10 per cent., the other a solution of nitrate of silver of 30 per cent. Next take a band of this paper, and cover it with a card, and expose it gradually to light by uncovering, successively, a portion at intervals of half a minute; lastly they are toned and fixed, and form the photergimetric scale.

When it is wished to make an observation, a band of the paper, prepared upon similar baths to those which have served for the preparation of the type band, is placed by the side of the scale; the instrument is carried to the place where we wish to examine the light, then count *five minutes*. At the expiration of this time the paper has acquired a tint which corresponds to one of the 20 gradations of the scale; we can then say that the light is of such and such a degree of the photergimeter, just as we say that heat is at such or such a degree of the thermometer.

To quote only a single example of the utility of this instrument, let us say that it often occurs to photographers, even the most experienced, not to know the exact time of exposure to give in cloudy weather, when the light may be said to be doubtful. Now it will be very easy for them, by comparing the indications of this instrument two or three times with the effects of their objectives, to have a sure guide under all circumstances.

The photergimetric scale should be placed in a portfolio contrived to hold bands prepared for experiments; we can keep a stock of these bands a long time when enclosed in a bottle containing chloride of calcium.—*Bulletin Chimique*.

ON MALIC AND MALEIC ACIDS AS NEW ISOMERIC BODIES.

BY H. KAMMERER.

We employ in photography a liquid containing nitrate of silver and sugar of milk, in which papers impregnated with succinic acid, citric acid, or other substances, are immersed. After prolonged use, there is deposited in such a liquid crystals of a silver compound, the composition of which is

This salt is isomeric with malate of silver. Its acid, which the author calls *isomalic acid*, is obtained by decomposing the salt of silver by sulphuretted hydrogen. It is crystallizable, forming colourless, transparent crystals, belonging to the oblique rhomboidal prism system. It is bibasic, like malic acid, but its salts are different from the malates. Acid isomalate of ammonia is obtained by saturating the acid with ammonia, by evaporation, one part of the ammonia is disengaged, and a radiated crystalline mass remains, the composition of which may be expressed by the following formula:—

The neutral salt of potassa $C^4 H^4 K^2 O^5 + H^2 O$ forms lamellar monoclinic crystals.

The neutral salt of lead is wholly insoluble in water and does not dissolve in boiling water. The salt of silver forms a white precipitate, flocculent at first, insoluble in water, but which, heated with water, is transformed into microscopic hexagonal plates. This salt is fixed at 212° , which distinguishes it from the two known malic acids.

The salt of silver treated with iodide of ethyl gives the ether $C^4 H^4 (C^2 H^5)_2 O^5$.

This body forms a liquid more dense than water which dissolves and decomposes it. The author has not obtained the amide.

The isomalates, treated by perchloride of phosphorous, furnish a chloride isomeric with chloride of fumaryl, which has been obtained from the malates. It is a yellow liquid of a penetrating and suffocating odour. It cannot be distilled without decomposition, and the water gradually decomposes it into hydrochloric acid and *isomaleic acid*, isomeric with fumaric and maleic acids. *Isomaleic acid* is bibasic; it is more soluble in water than fumaric acid is, but less so than maleic acid. Its composition is represented by the formula:—

Its potassa salt is deliquescent; the sulphate of lead forms a flocculent amorphous precipitate; the salt of silver is soluble in water, and by ebullition gives a metallic mirror.

The formation of the isomalic acid may be due to the oxydation of the succinic acid gradually formed in the liquid,

but, in this case, it ought to be identical with the acid obtained by M. Kébulé with bromo-succinic acid, from which, on the contrary, it differs. It is more probable that the isomalic acid is formed by oxydation of the sugar of milk.

ON THE COMPOSITION OF THE PHOTOGRAPHIC PICTURE.

BY EUGENE SAHLER.

The following experiments, to which I have been led by the theoretical hypothesis I published in May, 1862, which was repeated and commented upon by many theorists and operators who have more skill and leisure than I can boast of, may perhaps throw some light upon the subject of the

photographic image, and so contribute to the progress of the art.

1st Experiment.—I have washed in several waters a collodion plate sensitized in the usual manner so as to completely remove the excess of nitrate of silver. I afterwards immersed the plate in a saturated and filtered solution of binocide of barium.

During exposure I filled the camera with the fumes of hydrochloric acid, so as to place the film of iodide of silver in contact with oxygenated water.

The plate, when withdrawn, exhibited the usual opaline hue, without any trace of a picture.

To develop it with sulphate of protoxide of iron, it was first washed, else there would have been a formation of precipitated sulphate of barytes. The developing solution, then poured on to the plate, did not change its colour, and no picture made its appearance. After another washing I immersed the plate in the silver bath, and, at the end of a minute, I again submitted it to the action of the developer. The effect was immediate, the whole film blackened vigorously, and the picture, invisible by transmitted light, was clearly displayed by reflected light.

2nd Experiment.—To moderate the effect of the oxygenated water, I operated as described above, and diluted the bath of binocide of barium, exposed for twenty seconds, filling the camera with carbonic acid gas.

The plate, washed and immersed in a bath of nitrate of silver, strength 3 per cent., yielded a good picture; a slight reduction appeared over the entire plate.

In these two experiments, the film, composed only of oxy-iodide of silver, had not changed its aspect, and the developer alone had no action upon it. The striking analogy this case presents with the ordinary reaction, appears to me to merit serious attention.

My conclusion is, that the disturbance caused by light is rather a chemical combination, and that in the production of the picture, oxy-iodide of silver is formed.

A well known chemical observation had previously led me to adopt the hypothesis of oxydation: it is this:—*Chloride of silver, treated with warm nitric acid, does not produce aqua regia, as the other chlorides do, because, in presence of energetic oxydizers, it does not part with the chlorine, and there can only be a formation of oxy-chloride.*

The results obtained in the dry process, especially, seem to confirm this opinion, which, in fact, are the substances that succeed the best?

1. Resins and tannin, bodies which slowly absorb oxygen, an absorption which facilitates the oxydation of the sensitive film.

2. Albumen, which has an alkaline reaction; the alkalies and alkaline salts, which, in contact with the sensitive film, form double salts more easily oxydizable, as even the water of the bath can decompose them by losing its oxygen—a reaction so well known, that it has caused the rejection of alkaline baths, which veil the pictures.

3rd Experiment.—I next poured upon the sensitized plate a mixture of a small quantity of the sensitizing bath, with a few drops of the saturated solution of binocide of barium, the liquid remained clear. With a short exposure, the iron developer gave me an excellent negative. In this instance I washed the plate after exposure, and afterwards immersed it in the silver bath.

It is to be observed that the two oxydizers I have employed, the chlorate of potassa, in presence of nitric acid, and the binocide of barium, give such a solidity to the collodion film that varnishing may be dispensed with.—*Revue Photographique.*

DOINGS OF THE SUNBEAM.*

It is a relief to soar away from the contemplation of those sad scenes, and fly in the balloon which carried Messrs. King

Continued from page 382.

and Black in their aerial photographic excursion. Our townsman, Dr. John Jeffries, as is well recollected, was one of the first to tempt the perilous heights of the atmosphere, and the first who ever performed a journey through the air of any considerable extent. We believe this attempt of our younger townsman to be the earliest in which the aeronaut has sought to work the two miracles at once—of rising against the force of gravity, and picturing the face of the earth beneath him without brush or pencil.

One of their photographs is lying before us. Boston, as the eagle and the wild goose see it, is a very different object from the same place as the solid citizen looks up at its caves and chimneys. The Old South and Trinity Church are two landmarks not to be mistaken. Washington Street slants across the picture as a narrow cleft. Milk Street winds as if the cow-path which gave it a name had been followed by the builders of its commercial palaces. Windows, chimneys, and skylights attract the eye in the central parts of the view, exquisitely defined, bewildering in numbers. Towards the circumference it grows darker, becoming elongated and confused, and at one end a black expanse of waveless water is whitened by the nebulous outline of flitting sails. As a first attempt it is, on the whole, a remarkable success; but its greatest interest is in showing what we may hope to see accomplished in the same direction.

While the aeronaut is looking at our planet from the vault of heaven, where he hangs suspended, and seizing the image of the scene beneath him as he flies, the astronomer is causing the heavenly bodies to print their images on the sensitive sheet he spreads under the rays concentrated by his telescope. We have formerly taken occasion to speak of the wonderful stereoscopic figures of the moon taken by Mr. De la Rue, in England, by Mr. Rutherford, and by Mr. Whipple, in this country. To these most successful experiments must be added that of Dr. Henry Draper, who has constructed a reflecting telescope, with the largest silver reflector in the world, except that of the Imperial Observatory, at Paris, for the special purpose of celestial photography. The reflectors made by Dr. Draper "will show Debilissima quadruple, and easily bring out the companion of Sirius or the sixth star in the trapezium of Orion." In taking photographs from these mirrors, a movement of the sensitive plate of only one-hundredth of an inch will render the image perceptibly less sharp. It was this accuracy of convergence of the light which led Dr. Draper to prefer the mirror to the achromatic lens. He has taken almost all the daily phases of the moon, from the sixth to the twenty-seventh day, using mostly some of Mr. Anthony's quick collodion, and has repeatedly obtained the full moon by means of it in *one-third of a second*.

In the last *Annual of Scientific Discovery* are interesting notices of photographs of the sun, showing the spots on his disc, of Jupiter with his belts, and Saturn with his ring.

While the astronomer has been reducing the heavenly bodies to the dimension of his stereoscopic slide, the anatomist has been lifting the invisible by the aid of his microscope into palpable dimensions, to remain permanently recorded in the handwriting of the sun himself. Eighteen years ago, M. Donné published in Paris a series of plates executed after figures obtained by the process of Daguerre. These, which we have long employed in teaching, give some pretty good views of various organic elements, but do not attempt to reproduce any of the tissues. Professor O. N. Rood, of Troy, has sent us some most interesting photographs, showing the markings of infusoria enormously magnified and perfectly defined. In a stereograph sent us by the same gentleman the epithelium scales from mucous membrane are shown floating or half submerged in fluid—a very curious effect, requiring the double image to produce it. Of all the microphotographs we have seen, those made by Dr. John Dean, of Boston, from his own sections of the spinal cord, are the most remarkable for the light they throw on the minute structure of the body. The sections made by Dr. Dean are in themselves very beautiful specimens, and have formed the basis of a communication to the American Academy of Arts and Sciences, in which many new observations have been added to our knowledge of this most complicated structure. But figures drawn from images seen in the field of the microscope have too often been known to borrow a good deal from the imagination of the beholder. Some objects are so complex that they defy the most cunning hand to render them with all their features. When the enlarged image is suffered to delineate itself, as in Dr. Dean's views of the *medulla oblongata*, there is no room to question the

exactness of the portraiture, and the distant student is able to form his own opinion as well as the original observer. These later achievements of Dr. Dean have excited much attention here and in Europe, and point to a new epoch of anatomical and physiological delineation.

The reversed method of microscopic photography is that which gives portraits and documents in little. The best specimen of this kind we have obtained is another of those miracles which recall the wonders of Arabian fiction. On a slip of glass, three inches long by one broad, is a circle of thinner glass, as large as a ten-cent piece. In the centre of this is a speck, as if a fly had stepped there without scraping his foot before setting it down. On putting this under a microscope magnifying fifty diameters there come into view the Declaration of Independence in full, in a clear, bold type, every name signed in fac-simile; the arms of all the States, easily made out, and well finished; with good portraits of all the Presidents, down to a recent date. Any person familiar with the faces of the Presidents would recognize any one of these portraits in a moment.

Still another application of photography, becoming every day more and more familiar to the public, is that which produces enlarged portraits, even life-size ones, from the old daguerreotype or more recent photographic miniature. As we have seen this process, a closet is arranged as a camera obscura, and the enlarged image is thrown down through a lens above on a sheet of sensitive paper placed on a table capable of being easily elevated or depressed. The image, weakened by diffusion over so large a space, prints itself slowly, but at last comes out with a clearness which is surprising—a fact which is parallel to what is observed in the stereopticon, where a picture of a few square inches in size is "extended" or diluted so as to cover some hundreds of square feet, and yet preserves its sharpness to a degree which seems incredible.

The copying of documents to be used as evidence is another most important application of photography. No scribe, however skilful, could reproduce such a paper as we saw submitted to our fellow-workman in Mr. Black's establishment the other day. It contained, perhaps, a hundred names and marks, but smeared, spotted, soiled, rubbed, and showing every awkward shape of penmanship that a miscellaneous collection of half educated persons could furnish. No one, on looking at the photographic copy, could doubt that it was a genuine reproduction of a real list of signatures; and when half a dozen such copies, all just alike, were shown, the conviction became a certainty that all had a common origin. This copy was made with a *Harrison's globe lens* of sixteen inches' focal length, and was a very sharp and accurate duplicate of the original. It is claimed for this new American invention that it is quite "ahead of anything European;" and the certificates from the United States Coast Survey Office go far towards sustaining its pretensions.

Some of our readers are aware that photographic operations are not confined to the delineation of material objects. There are certain establishments in which, for an extra consideration, (on account of the *difficilis ascensus*, or other long journey they have to take,) the spirits of the departed appear in the same picture which gives the surviving friends. The actinic influence of a ghost on a sensitive plate is not so strong as might be desired; but considering that spirits are so nearly immaterial that the stars, as Ossian tells us, can be seen through their vaporous outlines, the effect is perhaps as good as ought to be expected.

Mrs. Brown, for instance, has lost her infant, and wishes to have its spirit portrait taken with her own. A special sitting is granted, and a special fee is paid. In duo tunc the photograph is ready, and sure enough, there is the misty image of an infant in the background, or it may be, across the mother's lap. Whether the original of the image was a month or a year old, whether it belonged to Mrs. Brown, or Mrs. Jones, or Mrs. Robinson, King Solomon, who could point out so sagaciously the parentage of unauthenticated babies, would be puzzled to guess. But it is enough for the poor mother, whose eyes are blinded with tears, that she sees a print of drapery like an infant's dress, and a rounded something like a foggy dumpling, which will stand for a face; she accepts the spirit portrait as a revelation from the world of shadows. Those who have seen shapes in the clouds, or remember Hamlet and Polonius, or who have noticed how readily untaught eyes see a portrait of parent, spouse, or child, in almost any daub intended for the same, will understand how easily the weak people who resort to these places are deluded.

There are various ways of producing these spirit photographs. One of the easiest is this. First procure a bereaved subject with a mind "sensitized" by long immersion in credulity. Find out the age, sex, and whatever else you can, about his or her departed relative. Select from your numerous negatives one that corresponds to the late lamented as nearly as may be. Prepare a sensitive plate. Now place the negative against it and hold it up close to your gas lamp, which may be turned up pretty high. In this way you get a foggy copy of the negative in one part of the sensitive plate, which you can then place in the camera and take your flesh and blood sitter's portrait upon it in the usual way. An appropriate background for these pictures is a view of the asylum for feeble-minded persons, the group of buildings at Somerville, and, possibly, if the penitentiary could be introduced, the hint would be salutary.

The number of amateur artists in photography is continually increasing. The interest we ourselves have taken in some results of photographic art has brought us under a weight of obligation to many of them, which we can hardly expect to discharge. Some of the friends in our immediate neighbourhood have sent us photographs of their own making, which, for beauty and clearness of tone, compare favourably with the best professional work. Among our more distant correspondents there are two so widely known to photographers that we need not hesitate to name them: Mr. Coleman Sellers, of Philadelphia, and Mr. S. Wager Hull, of New York. Many beautiful specimens of photographic art have been sent us by these gentlemen,—among others, some exquisite views of Sunnyside, and of the scene of Ichabod Crane's adventures. Mr. Hull, has also furnished us with a full account of the dry process, as followed by him, and from which he brings out results hardly surpassed by any method.

A photographic intimacy between two persons who never saw each other's faces (that is, in Nature's original positive, the principal use of which, after all, is to furnish negatives from which portraits may be taken) is a new form of friendship. After an introduction by means of a few views of scenery or other impersonal objects, with a letter or two of explanation, the artist sends his own presentment, not in the stiff shape of a purchased *carte de visite*, but as seen in his own study or parlour, surrounded by the domestic accidents which add to the individuality of the student or the artist. You see him at his desk or table with his books and stereoscopes round him; you notice the lamp by which he reads,—the objects lying about; you guess his condition, whether married or single; you divine his tastes, apart from that which he has in common with yourself. By-and-by, as he warms towards you, he sends you the picture of what lies next to his heart,—a lovely boy, for instance, such as laughs upon us in the delicious portrait on which we are now looking, or an old homestead, fragrant with all the roses of his dead summers, caught in one of Nature's loving moments, with the sunshine gilding it like the light of his own memory. And so these shadows have made him with his outer and his inner life a reality for you; and but for his voice, which you have never heard, you know him better than hundreds who call him by name, as they meet him year after year, and reckon him among their familiar acquaintances.

To all these friends of ours, those whom we have named, and not less those whom we have silently remembered, we send our grateful acknowledgements. They have never allowed the interest we have long taken in the miraculous art of photography to slacken. Though not one of them may learn anything from this simple account we have given, they will perhaps allow that it has a certain value for less instructed readers, in consequence of its numerous and rich omissions of much, which, however valuable, is not at first indispensable.

COPYRIGHT IN WORKS OF FINE ART.

THE new Copyright Act, passed last Session, has not given universal satisfaction, as not being sufficiently comprehensive in its objects, or specific and clear in its bearing on some points. Some remarks by a correspondent of the *Athenaeum*, and comments thereon by the Editor, will be interesting to photographers. The correspondent, Mr. F. W. Campin, says:—

Mr. Black, M.P., having given notice in the House of Commons of his intention to move in the next Session of Parliament that a measure be allowed to be introduced by him to consoli-

date and amend our Copyright Law (some remarks as to which I not long since communicated to you), I have forwarded the following suggestions on the subject for his consideration; and as they are, I submit, worthy of discussion, I venture to hope you may find a place for them in your columns. 1st. It appears to me there should be but one Copyright Act regulating copyright in all literary productions, in paintings, engravings, etchings, lithographs, &c., in sculpture, carvings, artistic casts and designs, in photographs and all original artistic productions; also in *architectural designs*. 2nd. That a simple and cheap registration, at Stationers' Hall, or otherwise, such as that now required by the Literary Copyright or Serjeant Talfourd's Act and the Artistic Copyright Acts, should be required; the effect of this registration should, as under those Acts, give the right to claim and sue for damages or penalties for all *subsequent* invasions of the copyright. Non-registration not to affect the copyright, but only the right of instituting legal proceedings in regard thereto. 3rd. The right to dramatise or versify (or to turn any drama into narrative, novel or otherwise, or a poetical production into prose), as regards any original literary production, should be reserved to the author if he announces his intention to reserve those rights, which he might do in a similar manner as he can now announce his intention to reserve the right of translation). These rights, like the rights of translation under the International Copyright Law, to be forfeited if the work be not dramatised or versified within a restricted period. 4th. If artistic designs are to be applied to articles of utility and manufacture, such, for instance and illustration, as drinking-vessels, articles of domestic or personal use, &c., then an additional registration under the Acts for Protecting Designs for Ornamenting Articles of Manufacture should be required. 5th. Fac-simile representations (or nearly fac-simile representations) of persons or of things, natural or artificial, produced by the use of photographic apparatus or other means of producing such representations, should have a copyright for a very short term only; for it can scarcely be maintained that the production of such representations involves the exercise of authorship, and I submit that there can scarcely be a true basis for copyright without authorship. It will become a crying grievance if a photographic manipulator can, by being the first in the field, secure the copyright in mere representations of the portraits of our public characters, and our most pleasing landscapes. 6th. With regard to *architectural designs*, the right to build according to any copyright design should be subject to be reserved to the author or designer in the same way and upon the same conditions that I have proposed with regard to the dramatising or versifying of literary works, in order to provide that if the originator of the design does not build within a restricted period, he shall not then prevent any one else doing so: his copyright in other respects, however, to remain intact.

In a following number the Editor makes the following comments:—

In Mr. F. W. Campin's communication to us on Copyright Amendment, as to *Photographs*, he says, "It will become a crying grievance if a photographic manipulator can, by being the first in the field, secure the copyright in mere representations of the portraits of our public characters and our most pleasing landscapes." No doubt, if such were the law, it would be a serious mischief; but the fact is, that no copyright exists in the *subject* of any work of Art. For example, if B executes a photographic or any other description of portrait of Lord Palmerston, all the copyright that B could possibly acquire in his work would be the right of preventing copies of that work being made without his permission. But that will not preclude any other artist from also taking a portrait of Lord Palmerston, and acquiring a copyright in his work, *provided only he has not copied that previously executed by B*. An indefinite number of copyrights may thus be acquired in the same *subject*. The Copyright Works of Art Act, 1862, which for the first time gave copyright in "every *original* painting, drawing, and photograph," by section 2, expressly provides that nothing in that Act contained "shall prejudice the right of any person to copy or use any work in which there shall be no copyright, or to represent any scene or object, notwithstanding that there may be copyright in some representations of such scene or object." The same principle equally applies to all works of literature and of music. The *subject* which an author selects is public property; and each author who writes or composes a

work upon that subject may acquire a valid copyright in his work, subject only to the condition that it is his own original production and not a mere copy or colourable imitation of the work of another person. As to the *title* which an author may adopt upon the publication of his work, he does, in most instances, acquire a priority over every other author or composer of a work upon the same subject; but only to such an extent as may be needful to prevent the public from being misled by supposing they are purchasing the work of A whereas they are buying that of B, who would thus unfairly intercept the profits which ought to accrue to A from his copyright.

Recent Patents.

A NEW PROCESS OF OBTAINING PRINTING SURFACES, DIES AND SUBSTITUTES FOR PHOTOGRAPHIC NEGATIVES. A communication from PAUL SCHULZE AND FREDERICK W. BILLING, of Brooklyn U. S.

The objects of this invention are, first, to procure a cheap substitute for wood engraving, from which to obtain, by the electrotype process, surfaces which can be printed from in the same manner as electrotypes obtained from wood engravings.

Second, to enable the process of etching metal surfaces to be performed more easily than by the mode heretofore produced.

Third, to obtain an easy mode of making dies for seals or for stamps of a similar character.

Fourth, to obtain by drawing, without the aid of a camera, or the agency of light, substitutes for photographic negatives, which may be printed from in the same manner as those negatives by the action of light acting through them upon sensitive paper.

The principal feature of the invention consists in first making a drawing in ink, which is soluble in water, upon the surface of a plate of glass or any other hard substance which has been previously coated with an alcoholic solution of shellac; then covering the whole surface with a coating of beeswax, or of a composition of beeswax, asphaltum and linseed oil, or other menstruum; next, immersing the plate in water for some time, and afterwards exposing its face to the action of a stream of water, by which the latter coating is washed off only from the lines of the drawing, and the whole of the drawing itself is washed away, leaving the latter coating between and among the lines of the drawing. The plate in this condition can be used in the same manner as a wood engraving to obtain an electrotype for printing, and with very little subsequent preparation for the other purposes herein above specified, as will be presently described.

In order to obtain the substitute for wood engraving, the plate of glass or other hard substance intended to receive the drawing should be made even, and have a fine grain given it by grinding with fine sand, rotten stone, or other suitable material. The first coating or ground of shellac solution may be applied either by pouring it over the surface, or by rubbing it on with a piece of cloth, and when it is dry it is ready for the drawing. The ink with which the drawing is made may be composed of a solution of gum arabic in water with enough sugar to prevent it from cracking off or separating from the plate when dry, and a suitable quantity of ivory black, lampblack, or any other colouring matter to make the drawing appear; or it may be composed of a weak solution of glue water, with any colouring matter, or of any coloured pasty substance soluble in water. The drawing may be made with a pen, brush, or pencil dipped in such ink. When the drawing has been completed, the second coating can be applied. It is preferred to use for this coating a composition of four parts by weight of beeswax, one part asphaltum, and one part rosin, with as much thin varnish, such as is used by printers for thinning their ink, or linseed oil, as will render the composition applicable with a lithographic inking roller or engravers' daub. The same end can be obtained with a coating of beeswax softened with spirits of turpentine, but with less sharp and clear lines. The necessary thickness of the coating will depend upon the character of the drawing, a thinner coating being sufficient for close fine work. After the application of this coating the plate is to be immersed in water. If the coating is thin, fifteen minutes immersion will be sufficient, but a proportionally longer time will be necessary for a thicker coating.

On the plate being removed from the water bath a stream of water is to be directed upon its face, and by that means the last coating is removed from the lines of the drawing, and the ink of the drawing all washed out, leaving the coating perfect between the lines of and around the drawing. In most cases the coating will remain sufficiently high to enable a good electrotype for printing to be taken from it; but when a higher ground is needed it can be produced by dusting lycopodium on the surface with a soft brush. Where the composition remains on the plate the lycopodium will unite with it, and by applying more of the composition over the surface with an inking roller, the lycopodium will be removed from the lines of the drawing, and the surface of the coating of composition will be further raised. Broad spaces between the lines, where a higher ground is necessary, can be raised by applying beeswax in the same manner as electrotypes now apply it to the surfaces of wood engravings, or by applying asphaltum with a brush. Before the plate is put into the hands of the electrotyper a thin coat of alcoholic varnish or linseed oil is poured on to it that the varnish or linseed oil in the ground may not prevent the deposit of the copper, and this coat of varnish will ensure the plumbago applied by the electrotyper being received and retained on every portion of the surface of the plates. In this way a substitute for wood engravings is obtained in a very short time at a small cost.

Instead of the drawing being made upon a plate, it may be made upon paper which has been first thoroughly saturated with alcoholic varnish, or any other substance, such as wax, that will make it perfectly waterproof; and after the drawing has been made, the back of the paper should be cemented to the surface of a perfectly flat plate, with beeswax or some other waterproof cement, and afterwards treated in the same manner as before described.

For metal etching the drawing is made with the soluble ink, in the manner above described, on the surface of the metal, and after it has been completed the whole surface of the plate is coated either with the etching ground commonly used by engravers, or with a ground of beeswax applied while the plate is warm, instead of with the second coating, which is applied to obtain the substitute for wood engraving, as hereinbefore described. The plate is then immersed in water, and afterwards exposed to the action of a stream of water directed upon its face to wash out the drawing, as hereinbefore mentioned, and the plate is ready to receive the acid for etching.

For making dies for seals or stamps of similar character, a drawing is made as at first described, and subjected to the same treatment up to the filling in of the broad spaces between the lines with beeswax or asphaltum, when it can be used as the mould from which to obtain a die in which to produce a seal by casting.

To obtain a substitute for photographic negatives, a drawing is made in the manner hereinbefore described, on a plate of finely ground glass, and after it has been made, instead of being coated with the beeswax, or composition of beeswax, asphaltum, and rosin, hereinbefore specified, a thin coating of that composition, with which some fine lampblack has been mixed, is applied. The plate is then subjected to the soaking and washing operations to remove the ink, and when it has dried it is dusted over with lampblack, by means of a fine brush, to make the ground still less transparent; after which the whole surface has applied to it a coat of alcoholic varnish. When this varnish is dry, the plate is used for printing upon prepared paper in the same manner as a photographic negative obtained by the camera. The drawings for etching seals and photographs have to be reversed, but for the first described purpose they should not be reversed.

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, August 11th, 1863.

At a recent meeting of our Society, M. Liébert, of San Francisco, offered some remarks upon the processes employed in the United States of North America to obtain ordinary or enlarged proofs. His communication referred especially to the following subjects:—

1. The suppression of tripoli, rotten stone, &c., in cleaning glass plates. These powders are advantageously superseded by a simple roll of china paper moistened with alcohol.

2. A small, simple, and convenient apparatus to hold the plates while being cleaned.

3. The complete restoration of the decomposed silver baths by the conversion of the nitrate of silver into bi-carbonate of silver, precipitated and re-dissolved without excess by nitric acid.

4. Direct positives upon thin iron plates, covered with Japanese varnish (Chinese lacquer), serving admirably for medallions, as these plates may be cut with chisels, and may be sent conveniently in a letter. These proofs have great delicacy, and are easily finished in a few minutes. The process is the same as for positives on glass.

5. Negative developing baths, giving also, immediately, the desired intensity without crude or harsh tones. This re-agent, on the contrary, gives great delicacy, and renders the model very vigorously. It is obtained in the following manner:—

Dissolve together

Sulphate of protoxide of iron	...	1 ounce
Nitrate of Potassia	...	¼ ounce

In

Rain or river water	...	14 ounces
---------------------	-----	-----------

Add

Pyroligneous acid	...	1 ounce
Alcohol, at 32°	...	¼ ounce
Silver bath solution, at 10 per cent.	...	½ ounce

Filter.

The collodion must be appropriate by being iodized with the re-agent indicated.

6. Toning proofs on albumenized paper with neutral salts of gold.

Solution No. 1.

Distilled water	...	20 ounces
Chloride of gold	...	30 grains.

Solution No. 2.

Distilled water	...	20 ounces
Bicarbonat of soda	...	120 grains.

Into ten ounces of distilled water put one ounce of the solution No. 1, and one ounce of solution No. 2. The proofs previously washed are immersed in this bath, and allowed to remain until they have acquired a blue-black colour, which takes place in four or five minutes upon moving the proof about in the bath; the toning being stopped by washing, the proof is washed and fixed in new plain hyposulphite of soda.

7. Toning with nitrate of uranium.

Solution No. 1.

Chloride of gold	...	15 grains
Distilled water	...	2 ounces.

Neutralize with bicarbonate of soda.

Solution No. 2.

Acetate of soda	...	100 grains
Water	...	32 ounces.

Solution No. 3.

Nitrate of uranium	...	15 grains
Distilled water	...	2 ounces.

Neutralize with bicarbonate of soda.

Mix and filter.

The proofs treated in these toning baths have remarkable vigour and warmth of tone.

Transfer the proof to waxed paper, or, which is better, coat it with a solution of caoutchouc; the proof finished and dried as though it were to remain upon the glass, is easily detached by a solution of

Alcohol (32°)	...	1 ounce
Nitric acid	...	10 drops.

which is left in the picture for about one or two minutes.

8. Photographic paper of extreme sensibility for direct

enlarged portraits upon chloride of silver, is obtained by a bath of acidulated ammonio-nitrate. The proofs are toned and fixed, and possess remarkable vigour.

9. A simplified and improved solar instrument, without reflector, which permits of the printing of proofs of very large dimensions, with perfect sharpness, and in a space of time one-fourth of that required by the French uegascope.

The instrument consists of a wooden box mounted upon a turning support, which permits of our continually keeping the sun upon the concentrating lens which projects the beam of light upon the negative, to afterwards design the picture upon the sensitized paper, which is at the end of the apparatus.

AN ENGLISH AMATEUR'S GLANCE AT FRENCH PHOTOGRAPHY.

SIR,—Arrived in Paris, my first visit was to the Quai de l'Horloge, the local habitation of most of the Parisian opticians, not forgetting Mons. Chevalier, I think in the Quai or Rue des Orfevres, and who most kindly directed and helped me to discover the whereabouts of one or two parties engaged in mounting choice microscopic objects. Curiously enough, the hotel to which I was bound was the Brittanique, the same at which you stopped; and I must say that I was well and reasonably treated. Never did a day pass by but I scrutinised the photographic productions, and cannot say that in all the length or breadth of the city did I see any downright bad pictures, or any touting abominations as I fear are too rife here. The even goodness struck me most forcibly; the large whole and half plate pictures seemed remarkably good, and the absence in the small carte de visite pictures of the multitudinous accessories here employed, but which were filled up by skill in posing, no one could pass unnoticed. Another fact appeared to be that the figures on the carte de visite were smaller than with us, and I also noticed that they appear to repudiate the use of very highly albumenized paper. This latter, I think, is a great step; since my return I have pointed it out to many of my photographic friends, and have obtained a supply of Marion's paper, which seems identical to that used in Paris, and with the phosphate of soda formula—

Soda phosphate	...	2 grs.
Chloride of gold	...	1 gr.
Water	...	8 ozs.

—the best pictures they have ever turned out have resulted.

Do you know how the peculiar pinkish hue (*nothing allied to red*) is obtained; several are shown, and very pleasing they were?

Already do I see that you have anticipated all I could say as to the pictures by Disderi, Numa Blanc, Ken, Petit, &c., and your lucid description of how the photographic sculpture statuettes which I saw at Bisson Frères' in, I think, the Quai d'Orsai, has done away with the apparent difficulty of chiselling by light. As the science, however, has arisen with M. Wilkeme, who must be a first class sculptor, and in whom the fact of making the resemblance lies, think you that the art will become general? Of course the Louvre must be seen, and here I saw an easel, the principle of which might be adapted to our wants as regards something suitable where copying is requisite. I am somewhat rough as a draughtsman, but here it is, such as it is.

E E are two upright posts with broad wooden bases. At A and D two cross bars are fixed at either end into the aforesaid uprights, between the cross pieces A and D, and in the uprights, a groove (*à la guillotine*) is made in which works a sliding bar, B, which at the back has a staple through which passes a cord knotted at X. At A is a ratchet wheel and catch, round which goes the other end of the cord of course; on B there

is a ledge, and it can be heightened or lowered as required. Now, if in addition to this a plank was extended from B, having at its other end two telescopic legs, we should have an apparatus at right angles to the print to be copied; and, with a short level and the legs, all could be brought into a plane. From inquiries I made, I was told they were very cheap and easily obtainable in London. Doubtless some of the drawing material houses may have the article.

Half a day next at the Palais d'Industrie, and the Photographic Exhibition for half a franc (five pence), and very cheap too, considering the many (I had almost said all), good Photographs there exhibited. A good deal, I think, I had seen over here, but for a specimen of photo-micrography, "The Flea," by A. Dunelle, No. 1102, must, I think, stand pre-eminent of its kind. I should say it must have measured at least from end to end three feet. The coloured glasses in the stereoscopes, were pleasing in some instances, but the effect struck me as being somewhat too abrupt.

When we see such magnificent landscapes as abound just outside Paris, is it not wonderful that this branch of photography appears to be the exception and not the rule. I am sure that the view of Sevres from the railway—I think the *rive gauche* of the Western Railway—would carry off the palm at any exhibition. Perhaps it has already been done, and my very pleasing remembrance of Versailles may have carried me beside myself. I cannot conclude my long letter without saying that the eight days I spent there were the most delightful I ever passed amongst strangers. I met with the greatest cordiality. I do not remember an instance in which I was imposed upon; and whenever (which was very frequent) I lost my way, and had occasion to inquire, the trouble and pains that were taken far exceed belief.

With an *au revoir* to Paris, believe me, my dear sir, yours very truly,
 JOHN BOCKETT.
 10, Willingham Terrace, Kentish Town, July 30th, 1863.

CUMULATIVE EFFECTS IN PHOTOGRAPHY.

SIR,—Photography is supposed by some to be perfect in itself. One glance of the lens at an object, one application of the sensitive coating, and one development is all that is considered necessary to produce a perfect negative, and, following up the same rule, one coating of the paper, and one exposure of it under one negative is believed by many the only course to pursue to procure a perfect photographic print. To these assumptions I demur, and I refer to Nature for the proof. All beautiful things in nature are produced by degrees, a certain effect is repeated, sunshine and darkness, moisture and drought, heat and cold, succeed each other, repeating their effects until the fruit and the flowers become matured. In like manner we should proceed to obtain a natural photographic representation of an object. The better to illustrate my meaning, I would refer you to the "Photo-Automaton Register," in my specification No. 1936, 3rd August, 1861, by which instrument several negatives can be taken of the same subject with varying degrees of exposure, but so placed that each will shut down in perfect register together. The subject may be landscape or the figure, the operation is the same. I take the negative that has been most exposed, shutting it down first on the prepared paper; I next change it for one less exposed, and, lastly, I apply the one that has been least exposed, and which may only show tops of trees, chimneys, or the tints in the folds of white dresses or clouds, until all are truthfully printed. The effect of such a course is to produce a print which for roundness rivals the stereoscope, and supplies the only means of getting the details of strongly contrasted subjects by the direct agency of light itself, avoiding the rude and imperfect attempts of hand-touching.—Your obedient servant,
 JOSEPH LEWIS.

29, Dame Street, Dublin, 1st August, 1863.

FORMULA FOR THE DETERMINATION OF THE COMPARATIVE DURATION OF EXPOSURE OF A SENSITIZED SURFACE IN THE CAMERA.

LET A represent the area of the aperture of the lens, F the focal length, and E the duration of exposure of a given surface, ascertained by experiment, and let A, or F, or both, be varied—required, the value of E, the amount of variation of A F being known.

Let *a f e* represent the variation of A F E.

$A + F$ gives the result E.

$$\frac{A E}{a} \text{ gives } x.$$

x here denoting the duration of exposure when F is invariable.

$$\frac{f^2 x}{F^2} \text{ gives } e.$$

e denoting the duration of exposure when A and F are variable, or *a + f* gives the result *e*.

Example of the application of this Formula.

Required the amount of exposure of a collodion surface, with 1 in. diameter aperture lens, 8 in. focus, it being known that with $\frac{1}{2}$ in. diameter aperture, lens of 6 in. focus (measured in each case from the back of the lens to the surface of focussing glass) required 30 seconds?

$$\frac{.196 \cdot 30}{.7845} \text{ gives } 7.45$$

$$\frac{64 \cdot 7.45}{.36} \text{ gives } 13.24, \text{ or } 13\frac{1}{4} \text{ seconds nearly.}$$

T. W. T.

[The formula is correct, although, perhaps, a little unnecessarily complicated; but it will be entirely vitiated if calculations are based on the "back focus," which is of no value for such calculations. The equivalent focus must always be ascertained, as it is the relation of aperture to equivalent focus which determines the amount of light.—Ed.]

Photographic Notes and Queries.

GLASS FOR DARK ROOMS.

SIR,—Most photographers are quite aware of the amount of gossip that there has been going on respecting non-actinic glass; but I have no doubt that few are aware that a window, say, 61 x 36, can be made perfectly impervious to the chemical ray for about 1s. 6d., in the following manner:—Say, for a light the size above named, go to an artists' colourman and get two tubes of raw sienna, and the same of orange chromic No. 3; mix them together, thin down to the usual consistency of ordinary oil colour with gold size (Japanese) and turpentine, and a small bit of patent driers; paint your window with it two or three times, carefully, and you will be charmed to see the beautiful golden tint it presents, and I may add that those who have been accustomed to work with a hole about 18 inches square, will, if they can command an ordinary sash window, do as I have done, will fancy themselves, not in a "dark room," but in a fairy land. Any one doubting the veracity of my statement can, when they have nothing else to do and can't sleep, call at 47, Baker Street, and convince themselves that it is no misstatement.—I am, Sir,

ONE LATELY BURNT OUT AT THE PORTLAND BAZAAR.
 August 7, 1863.

MEASURING THE ANGLE OF PHOTOGRAPHS.

DEAR SIR,—On seeing the letter of inquiry by "Tanno Glycerine" in the News the other day, I thought of a simple method of determining the angle included by any photographic lens. I had before me a view taken from the window of a house, with a No. 1 triple lens, on a 7½ plate. I cut two narrow strips of cardboard, say ¼ in. broad, and 6 in. long, jointed them at one end by a pin. I then placed the jointed

end as close as possible to my eye, and, placing myself at the window from which the view was taken, I extended the slips of cardboard till the angle thus formed included exactly the same objects as the photographs. On measuring the angle thus obtained with a protractor, I found it to be 50°. If this method is sufficiently correct, no photographer need have any difficulty in ascertaining the angle included by his lenses.—I am, dear sir, yours respectfully,

J. W. REFFITT.

[The method described may be used. We shall, however, shortly describe a neater application of the same principle.—Ed.]

Talk in the Studio.

ROYAL CORNWALL POLYTECHNIC SOCIETY.—We call the attention of our readers to the announcement in our advertising columns of the annual exhibition of this spirited and meritorious society. It will be seen that, amongst the awards to merit, a silver medal is set down for the best specimen of photography. Mr. J. C. Stephen, one of the oldest practitioners of our art, informs us that there is a small Art Union connected with the society, in which some of the prizes are usually photographs, and that he will be happy to render any assistance to photographers who may wish to dispose of their productions in connection with this enterprise.

A DISGRACE TO PHOTOGRAPHY.—A letter recently appeared in the *Daily Telegraph*, detailing an outrage which we regret should be possible even to the humblest and least scrupulous of those who practise the art. It says:—"A ruffian, who styles himself a photographic artist, established for the present in the Strand, was waited upon a few days since by a respectable young woman from the country, for the purpose of having her likeness taken; and on completion being, as she affirms, so totally deficient in resemblance, and wretchedly executed, she declined to receive it, and required another portrait. This was refused by the gentleman in attendance, who rudely informed her that he should not suffer her to quit the apartment until his demand was satisfied, if he kept her therein all night, using, at the same time, the most coarse and abusive language. He then locked the door, tucked up the sleeves of his shirt, and threatened to place her behind the fire-grate. In alarm and indignation she rushed to the window, to attract the attention of the police, and while doing so, this paragon of artists insultingly reminded her that she was showing her legs. After an imprisonment of upwards of an hour, an officer was summoned and admitted, who at once released the captive, and advised her to bring an action against Mr. B. for illegal detention, giving her at the same time his number to assist in such a measure, should its adoption be determined on. The affair will be strictly investigated; meanwhile, this statement may serve as a caution to female strangers in London, who may have the ill-fortune to be caricatured and imprisoned in like manner by a miserable pretender to a noble art, of which he has proved himself so utterly unworthy a disciple." In a subsequent number of the same journal, we find the following paragraph:—"Mr. J. Barry, photographer, of the Strand—in reference to a letter which appeared in our impression of Friday last, forwards us a communication in which he disclaims any share in the transaction referred to. Mr. Barry, we may add, was not alluded to in the communication in question."

To Correspondents.

W. G. H.—Some photographers object to the use of bromo-iodized collodion for collodion-albumen plates; but it is simply on the ground that if the collodion contain bromide the plates in their first stage should be kept from the light to avoid any chance of fog, whilst, if a simply iodized collodion have been used, there is less danger of the light acting upon the plate with its first coating. We use bromo-iodized collodion always; we believe Mr. Madd does so. You may use the mixture to which you refer, we should think without danger, but it will probably require thinning with ether and alcohol. 2. The condition of the bath for the first exciting is not very important; it may be neutral, or slightly acid with either nitric acid or acetic acid. Theoretically, the latter would be best; but in practice we have not found it important. 3. You can at any time neutralize nitric acid in a bath, either by the addition of freshly precipitated oxide of silver, in which case nitrate of silver would be formed, or with carbonate of soda, when nitrate of soda would be formed, which is inert in the bath. You can in either case add acetic acid afterward.

W. W.—The article on dry collodion to which you refer is, as you state, in many respects very valuable, but in some parts a little obscure. The use of the silver bath in which the plates were excited is undoubtedly meant, but we presume the plate is to be moistened with it by pouring on, not redipping. Mr. England's plan of keeping a bath of 10 grains of nitrate of silver to the ounce, with 5 minims of acetic acid, for redipping the plate, is a good one.

R. O.—You cannot treat a half-plate lens in any way to make it take card pictures in a room 7 feet long. You must have a lens of very much shorter focus, which would not define properly for a standing figure; or you must have a much larger room.

J. B. N.—We have never met with an ensé in which the gold in the toning bath of acetate of soda and chloride of gold was thrown down; but if from some unexplained cause it occur, the toning bath will be useless and will not tone. The print you enclose is certainly imperfectly toned. Try a fresh sample of acetate of soda; or read the article in our last on toning and follow the recipe there given. The formula you state is a good one, and need not be used in a more concentrated state. At present we do not see at what point the cause of your failure in toning arises. You use too much front light. Let us know of your further results.

UNA BOMBA.—It is quite possible to take very excellent portraits with a view lens; but it will be slower when stopped down subjeitely, than a portrait lens.

COANUS CHOUGH.—Send us one or two of the prints and we can better advise you. We shall then see possibly whether the faults be in the lens or the use of it.

GEORGE NEAL.—Send us a stamped and addressed envelope, and we will send you the address of a photographer from whom you can obtain lessons.

A. M. sends us two examples of paper excited on a bath of 20 grains nitrate of silver, and 60 nitrate of soda, both failures. We have not tried the process ourselves, nor can we say in what our correspondent has failed, but it is certain that he should have obtained better results than those forwarded to us. The bath should be a little acid rather than in any degree alkaline.

CHARLES FRANCIS.—A landscape background without gloss may be painted in flatting or distemper. If the former be desired, use oil colour mixed chiefly with turpentine, the smallest possible amount of oil being used. If you prefer the distemper, mix lamp-black and whiting with size to the proper consistency.

F. D. N.—We use the hypo bath made with one ounce of hypo in five ounces of water. It is impossible to say how much should be used for 100 prints without knowing the size of the prints, and even then it would be difficult to state absolutely. If the prints be card pictures you may use 2 or 3 ounces of hypo in 10 or 15 ounces of water, keeping them moving about all the time, and then after using that quantity throw the hypo solution aside.

J. BRAGESS.—Your pictures are all very good, both card and the larger one. We prefer the photography to the colouring. The latter is not bad, but the colours are a little too crude and glaring. The same skill in application with a little more dilution of the colours to secure delicacy of tint will doubtless give good results. We shall be glad to know your method. The print on resinized paper is very effective.

G. A. B.—The negative produced with iron development, without intensifying, certainly does not lack intensity. The prints generally are good, that with the single lens appears to have a somewhat abrupt perspective; and the lens is, we presume, of very short focus, too short for general purposes.

ANGLE-OMNIA.—A single view lens will generally give a circle of light of a diameter equal to the focal length of the lens; but the whole of that will not be defined without a very small stop, and even then straight lines will be curved in the margins. 2. In using the protractor to measure the angle, as we recently suggested, remember that the rule refers to the focus for parallel rays. If a very near subject be taken the focus is lengthened, and the measurement must be for the actual focus. That is, if the objects are so near that the focus of the lens is lengthened an inch, you must increase the length of the perpendicular set up on the base line of the picture by that amount; otherwise your calculations will be in error. We shall enter more fully into the subject shortly. 3. Yes; very complicated.

A CASE OF NEED.—Received from "W. D." 2s.; and from "Anon." 1s. 6d.

W. G.—We have often regretted that opticians leave so much doubt as to the real focus of the lenses in their catalogues. We cannot undertake in all cases to explain them with certainty. We believe the term "combined focus" has reference to the measurement from the back glass. We are not familiar with the lenses referred to as designated by various letters. You can easily ascertain the equivalent focus of the lens you have purchased by placing an engraving against the wall, and after obtaining an image exactly the same size on the ground glass, unscrew the lens and measure the distance between the ground glass and the engraving; one-fourth of that distance is the equivalent focus.

G. F. T.—With an ordinary quarter-plate lens you will have great difficulty in getting standing figures perfectly defined, without much stopping down, which will make the exposure long. For sitting figures it will answer better.

JOHN VANHEEM.—We learn on inquiry that the delay has arisen from the illness of the manufacturer. The reason you have not had an answer to your letters appears to have been the result of oversight.

NEXT YEAR'S PHOTOGRAPHIC EXHIBITION.

WE are glad to announce that notwithstanding a heavy loss to the Photographic Society incurred by the last exhibition, arising from a variety of causes beyond control, it has been resolved by the council that the idea of foregoing an exhibition next year, at one time entertained, will not be carried out. A sub-committee is already appointed to take time by the forelock, and secure, if possible, a suitable room for a desirable season.

We regard photographic exhibitions of most vital importance, not only as landmarks of efforts and opportunities of illustrating to the public the advancement of the art; but also as incentives to efforts and aids to improvement, in a degree not easily over-estimated; and we have learnt this determination on the part of the council, therefore, with great interest. Having regard also to the reasons given, we cannot say that we are surprised that the council have been driven to another determination, just announced: that of charging non-members of the society with a certain portion of the expenses of the exhibition, in the form of a small rent for space. This cannot be regarded as unreasonable. The holding of an exhibition in the heart of the best part of the metropolis, advertising it, engaging attendants, &c., involves a heavy outlay of money, which is paid out of the funds contributed by members of the society. When they exhibit, they are merely availing themselves of the opportunity afforded by the expenditure of their own money. If it were not expended so, they could have its value in the shape of presentation prints, &c. But if non-members have the same privileges of exhibition, sale of duplicates, &c., which belong to members, they have such privileges at the cost of members of the society, and a manifest injustice is perpetrated.

As to the question of precedent or practice, it is not worth while discussing it, as examples might be cited both of charging non-members, excluding non-members, and admitting them to all privileges of exhibition scot-free. In the present instance it is manifestly just, as well as expedient, since it is alleged that some of those who have exhibited largely and profited largely by their exhibition, have declined when solicited to become members of the society. Photography, as a profession, has been very profitable to many; as an accomplishment it has been a great delight, and its own exceeding great reward to many more; and it is a somewhat humiliating thought that the expenditure of a guinea a year should be grudged by those who can afford it, for the maintenance of a representative society to uphold the general interests and dignity of the art on all necessary occasions, whether by exhibitions or any other means. To say that the society is managed with less energy than it might be, is simply to complain of supineness in individuals, as the whole would be more energetic if every part were more active; and any who hold aloof because they are not quite satisfied with the society as it stands, simply fail to avail themselves of the opportunity, by their own personal influence, of effecting some improvement. We recommend

at least all who have any idea of profiting by the opportunity of exhibiting next year, to become members of the society as soon as it opens its winter session. We append a short article from the journal of the society, announcing the decisions to which we have referred:—

“At a numerously attended meeting of the Council of the Photographic Society, held at King's College, on the 4th inst., the subject of the Annual Exhibition of the Society was brought under consideration. The Exhibition of the present year has shared the fate of nearly all others which have taken place since the great international gathering at South Kensington, and has left a considerable deficiency to be made good from the resources of the Society. It has been unanimously determined, however, by the Council that we shall not abandon our annual display of the progress of our art, and that every exertion shall be made to obtain a suitable gallery for the purpose, where the public may view the photographs during what is generally known as the London season. A committee of three gentlemen practically acquainted with the subject, have been appointed as a committee to carry out the wishes of the Council and to whom every detail of the working of it will be entrusted. The Council, at the same time, resolved that it should truly be an exhibition of the “works of the members of the Society;” and although other photographers, not members, should be invited to contribute, they must not consider themselves aggrieved by being charged a certain rent for space, which will only be given after the requirements of the members have been supplied. This change from former years has been thought needful, from the large number of pictures sent by contributors who have no connection with the Society, otherwise than for the display of their photographs, and who largely profit by the sale from their exhibition. The Secretary drew attention, in illustration, to the fact that, having written to a well-known photographer (who has yearly exhibited and profited much by the Exhibition), to ask if he would be desirous of joining the Society as a member, he was informed by him that he saw no use in *any* photographic society, but would wish his own pictures to be all favourably placed on the line of view. There has been some delay in finishing the dies for the medal which was awarded at the close of the present season, in consequence of the great demand for such works on the occasion of the marriage of the Prince of Wales. We may rely on having them speedily completed; and thus early intimate that a series of prize medals will again be distributed to the best artists in the several classes of photographic art. The award of the gentlemen who so kindly gave the subject of the distribution their careful study, met with general approbation; and two gentlemen to act as judges, who need not be members of the Society, will be requested to give their aid in a similar manner on the forthcoming occasion.”

PHOTOGRAPHS IN PRINTING INK.

WE have received from Mr. Ponney a specimen of his new carbon process printed on mica. The prints so produced possess great delicacy, and from the perfect transparency of the medium it presents greater facilities for obtaining perfect purity of colour than paper. Except for very small miniatures, however, we prefer the effect of paper. The

mica has, moreover, if mounted on card, a tendency to separate in portions, giving a blistered effect.

From the experiments we have made we have arrived at the conclusion that it is much better to over-expose than to under-expose; that a soft, delicate negative is better than a very vigorous one; and that it is most desirable to print in direct sunlight. If the print be over-exposed, it is not worthless, as it becomes a very fine transparency; but if it be under-exposed it is devoid of half-tone and very unsatisfactory. If the negative be very dense, especially if it be printed in the shade, it not only requires very long exposure, but has a tendency to excess of contrast, yielding a vigorous, but hard print; whilst a thin, but good, negative yields very soft, and at the same time vigorous results. If the printing be effected in a dull light the length of exposure appears to be increased in a ratio greater than we find with silver prints. We have with soft negatives obtained good prints with an exposure of from half an hour to forty minutes in direct sunlight; and, in one instance, from over-exposure, a fine transparency in three-quarters. On the other hand, a few days ago we exposed some in Leamington, at Mr. H. P. Robinson's establishment, with very fine, but vigorous negatives, for about four hours in dull diffused light, and obtained a hard picture after all.

As regards the final result, there is, as we have before said, still something to hope for. Whilst, as regards half-tone, nothing is wanting, the gradation being as perfect as in a silver print; there is a want of the rich colour and bloom of a good silver print, and there is a want of the velvet-like blacks and pure whites of a good engraving. The colour, we think, may be improved by the addition of certain suitable pigments in the first preparation. But there will, we fear, be a slight want of brilliancy and purity in transparencies mounted on card, deriving the character of their lights from the white card on which they are mounted. We have found that mounting them on card having a very slight tint of pink or buff, gives great warmth, without any appearance of positive colour. Something is to be done by experiments in this direction, but we adhere to the conviction that it is to a method of transferring the prints to plate paper we must look for the finest results. If this can be effectively done, we see no reason why we should not have pictures with the brilliancy, purity, and permanency of engravings, with the detail, gradation and truth of photographs. The original preparation of the paper will require modifying to render it suitable for this purpose, requiring probably a greater body of ink which must contain a larger proportion of fatty matter. One attempt which we made to transfer, with the paper prepared for retaining the impression, was a signal failure, no trace of the ink passing to the transfer paper, notwithstanding that the attempt was made whilst the ink was quite wet from the bath of turpentine in which final washing from the superfluous ink had been effected.

Mr. Sutton states that in the course of his experiments with the process, he has just made an improvement in the original preparation of the paper, for which we shall look with interest.

FORMIC ACID IN THE DEVELOPER.

Mr. MALONE, writing in a contemporary recently, says, "Considerable discussion has arisen upon the subject, and much evident misconception prevails." He then adds, to illustrate, "A contemporary writer, for instance, hastens to publish a reclamation of Mr. Lyte's, which shows that a further exposition of the nature and claims of the new process is needed." He then proceeds to make the needed exposition by giving similar details of Mr. H. Claudet's operations to those we had published some weeks previous. A re-perusal of our remarks on Mr. Lyte's claim will convince Mr. Malone that the misconception to which he refers rests entirely with himself. Mr. Lyte made no reclamation from Mr. Claudet, nor did we publish any. Mr. Claudet

never made any claims as to originating the use of formic acid. He very liberally described a process of using it which he had worked out successfully, and we had the pleasure of publishing his communication upwards of twelve months ago, and describing the very fine specimen of its results with which he favoured us at the time. We believe Mr. Claudet's claims to the especial combination upon which his success depends have never been doubted. Mr. Maxwell Lyte's reclamation referred to an inadvertency of our own, and, therefore we hastened to publish it. We had stated that the use of formic acid in photography originated, we believed, with the Rev. J. Lawson Sisson, in 1853. Mr. Lyte informed us that he had published it some months previously in the same year. His reclamation had reference solely to the original use of this acid in the developer. We do not remember any specific reference to the accelerating character of formic acid until 1861, when MM. Ferrier and Sonlier made some such claim, but without publishing any particulars.

The first published formula with direct reference to its qualities as an accelerating agent, was given in the PHOTOGRAPHIC NEWS, two years ago, by Col. Stuart Wortley, writing to us from Italy, where he had been using the process with great success. The specimen we then received was one of the most charming we have ever seen; and the grand instantaneous views taken in Italy, which obtained a medal at the last Exhibition of the Society, fully confirm the value of the process. A correspondent of the *Photographic Notes*, who has recently been working the panoramic lens at Lisbon, writes that he is just about to try it for instantaneous sea views, "using," as he says, "Lieut.-Col. Stuart Wortley's developer, with iron and formic acid." We have no doubt, that he will succeed. Col. Stuart Wortley's instantaneous views were produced with a lens upon which, at one time, the stigma of slowness was cast—the achromatic triple. It is to be remarked also, that he uses a very acid bath, a much as two or three drops of nitric acid being added to each ounce of silver solution; and also a highly bromized and highly alcoholic collodion. With these he secures all the conditions of rapidity, delicacy, and brilliancy in a degree rarely equalled, and never surpassed.

MAJOR RUSSELL'S RECENT MODIFICATIONS IN THE TANNIN PROCESS.*

Few men have ever devoted more persistent and consecutive attention to the working out and perfecting of an idea in connection with photography than Major Russell has done in the tannin process. For three years he has steadily experimented with the process he invented, in its every phase and modification. Always courteous and accessible, he has been willing to exchange ideas with all interested in the matter, receiving and weighing suggestions, and communicating information with equal readiness and good will. Such a course could not fail to secure progress, and we are quite prepared for the announcement in the preface to his new edition that "since the publication of the first edition the process described in it has been greatly improved."

The chief improvements in result are greatly increased sensitiveness, better and softer pictures, and the facility of working on the plain glass without a substratum of gelatine. The chief improvements in method consist in the free or exclusive use of bromides, in the use of alkaline development, and in production or selection of the most suitable qualities of collodion. A great portion of the new edition is entirely re-written so as to re-state carefully all the desirable conditions in their most suitable form, and much new matter is given. If the photographer fail in obtaining good results with the tannin process, it cannot be from lack of information, for we do not remember that any single process in photography has

* "The Tannin Process." By C. Russell. Second edition. London: J. W. Davies.

received such perfectly and conscientiously detailed explanation as we find in the little volume before us.

PRELIMINARY COATINGS.—Notwithstanding that the gelatine coating may be dispensed with, the author considers it in most cases an advantage, and that, as it involves less care in cleaning plates, the amount of extra trouble is balanced. The gelatine solution, as now recommended, should contain both an iodide and a bromide like collodion.

The method of preparing it is given as follows:—

Soak twenty grains in eight ounces of distilled water and four drops of glacial acetic acid. When thoroughly swelled and transparent, dissolve by warming. Should the water be heated before the gelatine has had time to swell, the latter will adhere to the bottom of the vessel containing it, in a stiff glutinous state, and will dissolve with great difficulty. Dissolve three grains of iodide of cadmium, three grains of bromide of cadmium, and a small piece of iodine in a few drops of water, and mix with the solution; then filter two or three times through white filtering paper in a warm place. The acetic acid coagulates the white impurity, which then collects into filaments, and is removed by filtering, leaving the liquid very bright. This solution will keep well without alcohol, and it is better not to add it, as it tends to produce ridges in the film of gelatine, especially when present in large proportion.

A coating of india-rubber dissolved in benzole may be used instead of the gelatine. One grain of india-rubber sliced very thin is to be dissolved in an ounce of benzole, and then filtered. As Major Russell states that some difficulty is found at times in getting the india-rubber to dissolve, we may remark that we have found solution much more easily effected if just sufficient chloroform to cover the india-rubber be poured over it first. This readily dissolves the india-rubber, and the proper degree of dilution may be secured by adding benzole afterwards. The coating of india-rubber should be dried by the fire.

COLLODION.—One of the most important chapters is that on suitable collodion, a subject which has manifestly occupied much of the authors' attention. He says:—

Almost any collodion will produce good results with tannin if properly managed, no matter how new and horny or how old and rotten. Even should it be too old or too new to work well in the wet process, it will still succeed. Some difference will, however, be found in the character of the resulting pictures, though not so great as in the wet process, and there will be a great difference in the sensitiveness. A new collodion is the most sensitive, and in the writer's hands gives the proper red tone and vigour of negative perfectly. An old and powdery sample on the other hand, even if rendered colourless by cadmium, besides being very insensitive, gives a pale grey image which will not develop with quite so much vigour and richness of tone, and the film, when varnished, is soft and liable to injury, whereas that produced by a new and horny collodion is, in hardness and durability, only inferior to albumen.

Simply iodized collodion may be used, but the presence of bromide greatly increases sensitiveness. Any collodion which is sensitive, and gives good results in the wet process, if it does not contain iodide of potassium, may be rendered suitable for use with tannin in the following manner:—If the collodion is not iodized, to one ounce of iodizing solution* add three drachms of alcohol, s.g. .805, and fifteen grains of bromide of cadmium. If the collodion is already iodized, dissolve ten grains of bromide of cadmium in six drachms of plain collodion and two drachms of alcohol s.g. .805, and mix three parts of this bromized collodion with eight parts of iodized collodion. If so large an addition of bromide is found to retard the setting of the collodion too much, as may possibly be the case with some kinds, a smaller proportion must be used.

Positive collodion will require less bromide, as it usually contains some already; but the exact proportion of iodide and bromide is not of much importance. The addition of bromide of cadmium to collodion iodized with iodide of potassium produces, by double decomposition iodide of cadmium and bromide of potassium: the former impairs the fluidity of the collodion, and the latter, being nearly insoluble in strong alcohol, is

almost all precipitated. If, therefore, the presence of iodide of potassium in iodized collodion is shown by turbidity on the addition of bromide, it will be better to dissolve equal parts of bromide of ammonium and bromide of cadmium in the smallest possible quantity of alcohol s.g. .816, and to add this solution cautiously until turbidity is produced. The collodion will be found to be very little altered in fluidity, and, when cleared by subsidence, to have retained enough bromide to improve it greatly for this purpose; but from its admitting of the use of but little bromide, such collodion cannot be expected to give a great amount of sensitiveness.

Should any doubt be entertained as to the good effect of so large a proportion of bromide as that rendered above, it may be easily removed by the following experiment:—Prepare nine different portions of the same collodion in such a manner that the first contains only iodide, the second one part bromide to eight iodide, and so on, increasing the proportion of bromide by one-eighth in each until the last contains equal parts of iodide and bromide. If a tannin plate is prepared with each of these portions it will be found on trial that the first addition of bromide has greatly increased sensitiveness, and that considerable increase is gained by farther additions up to three parts bromide to eight of iodide; after this, the increase of sensitiveness with each successive addition becomes less. Between one part of bromide to two of iodide, and equal parts of each, the difference is not very great, but sensitiveness continues to increase with every addition of bromide, and, as recent experiments seem to show, the greatest sensitiveness is obtained by the use of bromide alone; this, however, requires different treatment, and when iodide is used at all it is not usually advantageous much to exceed the proportion of three parts bromide to five parts iodide.

Successive additions of bromide, up to equal parts of iodide and bromide, do not seem to diminish intensity, but they increase the tendency to blurring with the same exposure; this may, however, be only the effect of greater sensitiveness. A very large proportion of bromide is likely to impair too much the setting of some collodions, and during the long stay in the bath rendered necessary, crystals containing iodide are apt to form on the film, even when the nitrate solution is not over-iodized.

Bromide of silver forms a transparent combination with the collodion, to a greater extent than iodide of silver; a greater weight of iodide and bromide together should therefore be used in a given quantity of collodion, than of iodide, if it alone were employed, otherwise the film would be less opaque. The different proportions of iodine and bromine in various iodides and bromides, and peculiarities in the quality of the pyroxyline, might slightly affect the proportion of bromide which can be used consistently with working well.

Collodion which gives a dense and horny film works well with tannin, but a somewhat porous film is more sensitive. A porous texture may be obtained by preparing the pyroxyline in acids at a high temperature, but it seems better to produce the effect by using a full proportion of water at a moderate temperature; still greater sensitiveness may in this way be obtained, the pyroxyline is more soluble, and the collodion becomes clear by subsidence more quickly.

Bromo-iodized collodion will produce good results, but simply bromized collodion is strongly recommended as being in most cases preferable; the latter is about twice as sensitive as the former; and seems, so far as it has been tried, to have no tendency while in the exciting bath to form the needle-shaped crystals which are so common an annoyance when the collodion contains iodide. Above all, the bromized collodion will produce a better negative when the subject presents great contrast, such as sky and dark objects, as it will bear over-action of light better, and shows no tendency to produce blurring along the edges of the strongly lighted parts of the subject.

Bromized collodion seems to be particularly suitable for use with tannin. In a great number of trials with different kinds of collodion, and various modes of treatment, the iodide and bromide in no one instance approached the bromide in sensitiveness, even when the latter was used in a much less sensitive collodion, or in quality of negative with a landscape subject when both were exposed long enough for the darkest parts.

Two precautions are necessary when bromide alone is used: First, not to use a very slow-setting collodion—probably almost any sample intended for the wet process will answer; second, to excite in a strong bath, and keep the bath in long enough.

* If this contain iodide of potassium, which may be known by its becoming turbid on the addition of bromide of cadmium, it will be better to prepare a fresh iodizing solution by the formula to be given.

It is much easier to make pyroxyline suitable for bromide than for iodide, as in the former case the point of solution must not be so nearly approached as would be desirable in the latter. Besides this, the sensitiveness of bromide does not seem to be so much affected as that of iodide by the mechanical state of the collodion.

Many experiments have been made to ascertain the best kind of pyroxyline for use with bromide. Three parts of sulphuric to one part of nitric acid will give a kind which works well, but is rather deficient in sensitiveness. When equal parts of sulphuric and nitric acid are used, the collodion flows well and is very sensitive, but has too little setting power. Two parts sulphuric acid, and one nitric acid, seem to produce the best results on the whole. The formula already given does not make a collodion which will set quickly enough; but, if modified in the following manner, answers at least as well as any which has been tried:—

Boil a quarter of a pound of the best American cotton for two hours in a gallon of water and two ounces of caustic potash, as recommended by Mr. Hardwich; then wash by alternately holding under a stream of water and pressing strongly between the hands. In this way the potash is removed much more quickly than by soaking. If worked well the whole time, about twenty minutes' washing will be sufficient. Dry thoroughly, and immerse in the acids at a temperature of 125°, and keep in for twenty minutes; wash in the same manner as after the potash. After about fifteen minutes press out the water well, and pour on the pyroxyline as much weak solution of bicarbonate of soda as it will hold; then wash well again in the same manner as before. In all points not specified Mr. Glover's formula is to be followed.* The gain in weight should be about fifty per cent.

This pyroxyline is very soluble, and makes a bright collodion which is fit for use in a short time; sets, if anything, too quickly, and keeps very clean in developing, but is not very fluid. If the collodion is not found to flow freely enough, it may be mixed with some made by Mr. Glover's formula. It is much easier to regulate the quality of the collodion in this way, by varying the proportions, than to make a sample of pyroxyline which will give exactly the qualities required; but, if preferred, the temperature of the acids and time of immersion may be intermediate. For instance, the temperature 135° to 140°, immersion about fifteen minutes.

BROMIZED COLLODION.

Pyroxyline	5 grains.
Bromide of cadmium	8 do.
Alcohol '805	4 drachms.
Ether	4 do.

Put the whole in a tall, narrow bottle, shake up until the solution of the pyroxyline and bromide is complete; then allow to settle, clear, and decant. If the alcohol is weaker, or if the pyroxyline is of a kind likely to give too little setting power, a larger proportion of ether should be used.

No fear need be entertained that the bromide will burst out like iodide, if even in larger proportion than that given above; but if the collodion is of an unsuitable kind, and will not set well, irregular markings of unequal thickness in the direction of the dip may be formed, and, if so, will be plainly visible by transmitted light, although the surface, when dry, will probably be quite bright.

The addition of a few drops of a strong alcoholic solution of bromine† to an ounce of the collodion, seems to be an improve-

* Mr. Glover's formula, given on a former page of the work, is as follows:—Prepare the cotton by boiling in a five-per-cent. solution of pearlsh; wash thoroughly from the alkali, and dry perfectly.

Sulphuric acid, 1 '845	5 ounces.
Nitric acid, 1 '370	2½ "
Water	1 drachm.

When the temperature sinks to 145°, immerse two and a half drachms prepared cotton, in tufts of not more than thirty grains each, taking care that each tuft is well saturated. Cover up for ten minutes. Then lift out with two glass spatulas, squeezing out as much of the acids as possible, and throw into a large quantity of water, separating the cotton so as to dilute the acid as quickly as possible. Change the water every five minutes, six times, well squeezing between each change, during which time it must have the sole attention, as I find the more rapidly it is washed the more soluble is the product. To the last change of water add ten grains bicarbonate soda, which neutralizes the last traces of acid without affecting the nature of the pyroxyline. Rinse and dry rapidly.

† To make this solution, pour three fluid ounces of alcohol, s.g. '805, into a thin beaker, and place on the far side of a bottle of strong solution of ammonia from which the stopper has been removed. To avoid the ill effects of the noxious fumes of the bromine, do not remove the stopper from the bottle which contains it until it is held beyond the ammonia, and keep it

ment, but bromine can only be used with a quick-setting collodion, as it tends still more than bromide to retard the setting. The yellow colour given by the bromine will probably soon disappear, but the collodion will retain an acid reaction.

The bromized collodion should be excited in a sixty-grain bath, and should be kept in for about fifteen minutes. If the formula given above is followed, the film will be very creamy. The collodion may be made much thinner by the addition of ether and alcohol, and it can then be excited in a weaker bath, and more quickly.

When both are prepared with a weak solution of tannin, and developed in the ordinary way with nitrate of silver and acid, the bromized collodion is far more sensitive, and gives better results than bromo-iodized collodion; but the former develops much more slowly than the latter, and produces intensity with difficulty. With the alkaline developer, which will be described, the bromized collodion develops very readily, and easily produces ample intensity when tannin solution of sufficient strength has been used.

THE NITRATE BATH.—The nitrate bath may be used neutral or slightly acid with nitric acid. If for use with bromized collodion only, it is to be saturated with bromide of silver only. To prevent the accumulation of nitric acid it is recommended to filter the solution from time to time through filtering paper holding a little carbonate of silver. The author says;

Another good plan is to keep the bath solution in the dark room with carbonate of silver enough to form a deposit in the bottle about a quarter of an inch deep. If the bottle contains a much larger quantity of the solution than is required for use, it may be poured off clear without filtering; a little nitric acid may then be added. For this purpose dilute one part s.g. 1.360 with two parts water; one drop of this will be enough for from ten to thirty ounces of the bath. The exact quantity of acid necessary will depend on a variety of circumstances. This plan is better than the addition of iodine to simply bromized collodion, and appears to answer exceedingly well. If a little free bromine can be used in the collodion, much the same effect will be produced, with perhaps less loss of sensitiveness, and no acid need be added to the bath. The bath being neutralized every time after use, precipitates nearly all the little organic matter it may have acquired, and a very small trace of acid will keep the pictures clear, as the bath is always used in a freshly acidified state.

The amount of sensitiveness obtainable in this or any other process depends greatly on the smallness of the quantity of acid required to prevent fogging. When the bath is kept permanently in an acid state, the accumulation of organic matter will render more and more acid necessary. A bath treated as just described will give nearly the highest attainable degree of sensitiveness, and is not likely, if used with bromized collodion, to get out of order unless by absorbing in time a large quantity of alcohol. It will be as well to add, after pouring out for use, a small quantity of plain nitrate solution of the same strength as the bath, about as much as it wasted the last time used. A piece of thin filtering paper pressed over the mouth of the bottle, instead of the stopper, will keep out dust, and at the same time permit the escape of the ether, and of much of the alcohol, and of the carbonic acid liberated by the nitric acid from the carbonate of silver.

A strong bath is better than a weak one, as it enables us to use a thick and highly-iodized or bromized collodion, and so to produce an opaque film; in all cases it saves time by exciting more quickly.

It is recommended that plates for all dry processes should be left a longer time in the nitrate bath than is usual for the wet process, and especially where the collodion contains much bromide. The use of iodized gelatine for a preliminary coating also renders a longer immersion necessary.

Washing.—The mode of washing recommended is by the use of two successive immersions in distilled water, in a dipping bath, and then in two or three changes of common water in which the plates should lay not less than half an hour.

there as long as open. Pour into the alcohol about one ounce by weight of bromine cautiously, a little at a time, stirring with a glass rod, as much heat will be evolved. Cover with a glass plate, and when quite cold, pour into a bottle which stops well.

We must defer further comments upon, and extracts from, this valuable work until our next.

Scientific Gossip.

IMPROVEMENTS IN THE SPECTROSCOPE—BISULPHIDE OF CARBON PRISMS—ANALYSIS OF THE FIXED LINE D.

SINCE we last gave our readers any account of the spectroscopic and spectrum discoveries, several important improvements have been made in this branch of inquiry. One advance has been made in the angle and position of the prisms. In the ordinary instrument, in which prisms of 45° or 60° are employed, the light falls upon the first surface at a considerable angle, and, therefore, half of it at least is reflected from the polished glass to the sides of the box and is lost; the other half passing into the prism and being refracted both at its entrance and exit. For convenience of measurement, and for certain theoretical considerations, it is always recommended to place the prism in the angle of minimum deviation, or, in other words, in such a position that the incident and emergent ray shall make the same angle with the prism. Dr. Walcott Gibbs has recently had constructed an instrument in which an entirely new principle is involved. In this spectroscope the prism of flint glass has a refracting angle of 37° only. The beam of light, after passing through the slit, is rendered parallel in the usual manner by a collimating lens having the slit in its principal focus. It then falls on the first surface of the prism; but this, instead of being at an angle, is so placed that the ray of light meets it perpendicularly. In this case, therefore, there is no appreciable loss by reflection, but the whole of the light passes into the body of the glass without any refraction whatever. The bundle of rays then meets with the second surface of the prism, and, of course, makes with this an angle of 37° . The refraction in this case is very great, and it takes place at an angle so near the limiting angle that the refracted rays emerge nearly parallel to the second surface of the prism. The amount of dispersion produced in this way is very great, whilst the loss of light occasioned by reflection at the first surface in prisms of 60° placed in the position of minimum deviation is avoided. It will be evident, from a little consideration, that the refracted rays in an instrument of this construction diverge as if from a single radiant point situated on the second surface of the prism, and, therefore, the vertical axis of the instrument round which the telescopes rotate must be in a line with this second surface. The spectrum thus produced possesses remarkable intensity, and the dark lines are seen in countless numbers, and with great distinctness. The instrument in this form is sufficient for all chemical purposes, but it is so constructed as to permit the use of a second prism by which the length of the spectrum is, of course, greatly increased. Though the telescopes are only six inches in length, with a magnifying power of about six, the spectrum compares very advantageously with that of a large apparatus with telescopes of 18 inches focal length, and $1\frac{1}{2}$ inch aperture, and a prism of 60° .

An instrument possessing the most wonderful powers of resolving spectral lines has just been constructed for Professor Cooke. From an account given in a private letter, we believe that this instrument is the largest and most powerful ever yet applied to the spectrum. It has nine prisms, filled with bisulphide of carbon, having $2\frac{1}{4}$ inches aperture, with telescopes of corresponding size. By means of a conical wheel, against which the backs of the prisms rest, they are enabled to be adjusted with great facility to the angle of least deviation. Two pins on the back of each prism are so adjusted that when pushed against the wheel the back of the prism is tangent to the circle. By means of this simple contrivance, the adjustment can be made from one end of the spectrum to the other in a very short time. The prisms

are constructed on a plan suggested by Professor Rood. The frames are made of cast iron; after the faces have been worked nearly true, plane parallel plates of glass are cemented on the sides with a mixture of glue and treacle. After a few days, the bisulphide of carbon is poured in through an opening, which is then closed with a screw. So far, the construction of the prisms is old and attended with a most serious defect, which has, perhaps, prevented the general introduction of these prisms; for if the light from the slit be allowed to fall on the face of a prism thus prepared, and reflected from it along the axis of the observing telescope, it will be found that the image of the slit is *distorted* to a greater or less degree; further examination shows that the glass plate has been slightly bent by the hardening of the glue, the curvature in many cases being considerable. If two or more such prisms are used for the production of a spectrum, a certain amount of confusion is always seen amongst the fixed lines; plates of glass of even the fourth of an inch in thickness are constantly affected in this manner, and unless the evil be removed the prisms are of no great value. This difficulty is corrected by Professor Rood, in the following manner: The prisms are finished, in the way above described, with glass of good quality, then a few drops of olive oil are placed on one of the faces, and a plate of truly plane glass laid on it; the oil spreads out, and is held in position by capillary attraction; the four corners are then secured by four drops of melted wax and resin. Optical contact is thus secured, and the slight curvature corrected; each face is in turn thus dealt with. Large prisms of bisulphide of carbon thus corrected, while remarkably cheap, approach a degree of optical perfection not attainable by the best flint glass prisms yet produced, for even if the flint prism is of equal size with that of bisulphide of carbon, and optically unexceptionable, the fact still remains that the dispersive power of the latter is greater. The nine prisms of Professor Cooke's instrument are prepared in this manner, and as the light is here bent through almost 360° , we have reached about the limit of power, unless we can reflect back the rays over the same path.

This instrument has established the following points.

1. That the lines of the solar spectrum are as innumerable as the stars of heaven. It shows distinctly at least ten times as many lines as are given by Kirchhoff in his chart, and an infinitude of nebulous bands just on the point of being resolved. We have seen a drawing of the fixed line D of Fraunhofer as seen by it. Our readers will remember that it requires a very good instrument to see this line double at all. Kirchhoff, in his chart, only gives three lines, the two broad ones and a faint central one. Professor Rood found that three line lines were enclosed within this double line. By this new instrument of Professor Cooke nine additional lines are seen enclosed within D, one being a nebulous line which may be resolved into other lines upon an increase of optical power.
2. It proves that the coincidences between the bright lines of the metallic spectra and the dark lines of the solar spectrum remain perfect even with this greatly increased power. By it the two members of the sodium line can be spread so far apart that the $\frac{1}{100}$ th of the intermediate space can be readily distinguished, and yet the coincidence with the two dark Fraunhofer lines is still absolute.
3. It shows that many of the bands of the metallic spectra are broad coloured spaces, crossed themselves by bright lines. This is the case with the orange band of the strontium spectrum and with the whole of the calcium and barium spectra to a remarkable extent.

THE VALUE OF A WIDE ANGLE IN A PICTURE.

In a recent article in *Silliman's Journal*, Mr. Coleman Sellers has some good remarks on the value of including wide angle in a photograph. We cannot altogether endorse his remarks as to the want of progress in the chemistry of

photography, but cordially agree with him as to the optical improvements. He says:—

“Photography, with the discovery of the use of collodion, seemed to leap into its present high position at one bound, at least so far as the chemistry of the art is concerned. The negatives of to-day look like the negatives of the first experimenters, and the chemical process of their production is essentially the same. But with the optics of photography the case is different; here there has been a steady improvement. The wants of the portraitists have been met by the construction of new objectives suited to the style of pictures to be produced. In these instruments depth of field, with free admission of a large volume of light, was what was most sought for. Theory could not dictate what shape or combination of lenses would best produce this result; and patient experiments were resorted to. The requirements of landscape photography are quite different from those of portraiture. A portrait tube may be used to take views if it be provided with a stop or small opening to limit the amount of rays passing through it, and thus to deepen the field, or increase the “reach” of the instrument, as it is technically called. This involves loss of light, and consequently diminishes the quickness of its working. We hear continually of rapid or instantaneous photography, and are often led to believe that the rapidity is to be ascribed to some wonderful sensibility of the chemicals used; but this is only partially true, and to the optician is due the most of the merit of instantaneous pictures. A portrait tube with its full opening will, in a skylight room, produce a picture in perhaps ten or fifteen seconds. This same instrument, with the same opening and same chemicals, exposed to an extended view in bright sunlight, could not be opened and shut quick enough; the immense volume of light reflected from so large an area of space being concentrated on the same-sized plate, as in the first case, would be too violent in its action, and, from the nature of the instrument, near and distant objects could not be brought into focus at the same time.

“The human eye, when the head is at rest, takes in an angle of view of at least 70° or 80° , the whole of which is not seen clearly at once, but can be examined in detail by the almost unconscious rolling motion of the eye in its socket—the actual included angle of clear vision at any one instant being only 1° or 2° . Hence a picture of a landscape, for instance, to fill the eye and seem a true representation of nature, should include an angle of at least 60° . Ordinary instruments, such as have heretofore been used, do not include an angle of more than one-half this amount; and hence has originated the complaint that photographic views represent mere patches of scenery, and not pictures. I remember once standing on a bridge, camera in hand, and looking up the romantic Wissahicon. The picture presented to my eye was very beautiful—the centre a waterfall framed in on both sides by wild and rugged rocks, and spanned above by the arch of a railroad bridge crossing at the tops of the cliffs. The foreground was made up of a stony bed, where danced and foamed the rapid current. I planted the camera, and hoped soon to peel off from this charming view a cuticle (as Dr. Holmes says) which, like plates of mica, could be split and re-split for the collections of my friends. But on the ground glass I found nought but the tumbling water. No rocks, no bridge, no stony river-bed: the poor camera, in its empty head, was incapable of taking in the whole of the charming picture. One of the dreams of the photographer has been of an instrument which should embrace a large angle, and thus satisfy the wants of the eye; but with the majority of the attempts in this direction came other evils, the greatest of which was distortion of the marginal lines. The aplanatic lens of Grubb is said to comprise an angle of 70° ; but in a view before me of Trinity College, Dublin, taken with this lens, there is a curvature of the straight lines of the roof of more than one-eighth of an inch in its length. Mr. Sutton’s panoramic lens, a sphere

of glass filled with water, includes a very large angle over 100° , on the base-line; but the pictures are produced on curved plates, which require curved holders, baths, and printing-frames, and, in the case of architectural pictures, the right lines are distorted, unless the picture be bent to the curvature of the plate upon which it was taken, and thus viewed near the centre of the curvature.”

He then proceeds to describe in enthusiastic terms, the new globe lens, with which he appears to be much pleased. We cannot help being somewhat struck with the fact, that whilst Mr. Sellers and others in America writing on the subject, seem angry at what they conceive to be the want of appreciation this lens has received in England, they systematically overlook in their comparisons the triple lens, which, we have before observed, is equally free from distortion and superior to the globe both in rapidity, perfection of definition, and amount of angle included. If the triple lens did not exist, the globe lens would, from its wide angle and freedom from distortion, be a great boon to photographers; as the matter really stands, it was forestalled in this country by a better instrument.

M. CAHAGNET'S PRINTING PROCESS.

BY ERNEST LACAN.

At the moment when M. Wothly exhibited to us the excellent proofs he obtained by his new printing process, we learned that an experimentalist, whose name was not unknown to us, M. Cahagnet, was also in possession of an economical printing process. Wishing to satisfy ourselves of its merits, we set out one fine evening for M. Cahagnet’s rural retreat, in company with one of the most eminent Paris photographers, desirous merely of being satisfied as to the truth of what he had heard respecting the new method.

It was nearly sunset when we arrived at the door of the inventor’s dwelling. M. Cahagnet, who did not expect our visit, hastened to place before us the numerous results of his experiments, at the same time giving every explanation we required, concealing neither the difficulties to be overcome nor the pleasures of success, nor the hope of still more perfect success. We have had the good fortune to find ourselves very frequently, for several years past, in contact with many inquirers, investigators and inventors, and we came to the conclusion that our obliging host may be classed among the most sincere.

The proofs he exhibited to us are taken upon that sort of cardboard used for *cartes de visite*, and resemble very much in appearance collodion positives transferred by Moitessier’s process. They are remarkable for their delicacy and the great purity of the whites. The ground may be obtained white or tinted. The tones resemble those of an engraving, but, in our opinion, they have the defect of being rather heavy. We saw pictures of small dimensions only, without being so perfect as those obtained by M. Wothly, which surpass the best proofs obtained by the old methods—these results are in every respect satisfactory. With regard to the method, the following is from a letter on the subject, addressed to us by the author:—

“The enamelled cardboard proposed to replace the salted or albumenized papers for the production of photographic pictures, presents the following advantages over those papers.

1st. Its size is $26\frac{1}{2}$ by 20 inches, while that of the papers referred to is 23 by 18 inches.

2nd. The chloridizing and albumenizing being suppressed, these two substances are economized.

3rd. The sensitizing bath, costing only two and sixpence the pint, increases the cost of the sheet (sensitized on both sides, and giving, consequently, a double picture) only to twopence, which, added to the cost of the card, threepence, makes the cost only fivepence per sheet, while albumenized paper, being smaller and sensitized on one side only, costs tenpence.

4th. The time of sensitizing is only 25 seconds, while

that of nitrating is five minutes, consequently a man may sensitize in one hour as many as would require, under ordinary circumstances, a whole day.

5th. This cardboard may be kept sensitized as long as a month, or even longer, without losing any of its good qualities, an advantage offered by no other kinds of paper hitherto. From this property it can be sent to any distance, or kept in the operator's portfolio until it is convenient to use it.

6th. The time of exposure to light is the same as with other papers.

7th. Fixing is accomplished by means of a simple washing in running water for a few minutes.

8th. Toning is dispensed with.

9th. This cardboard endures immersion in alcohol varnishes or fatty substances. Colouring, and, consequently, painting, may be applied to it without causing any change in it. This is an additional protection against atmospheric influences.

10th. Being exposed to no destructive fixing agent it yields faithful positive proofs.

11th. It can be formed into albums and books, the picture being visible upon both sides.

12th. I have possessed for more than a year a large number of pictures obtained upon this cardboard. I have recognised no change in the pictures, nor in the pure white grounds you have seen.

You know very well, sir, that in photography any innovation concerning papers proposed for the production of pictures raises, above all things, the question of time, while those concerning sensitizing or developing baths for negatives can be appreciated instantly. It is therefore very difficult for the students of this question to speak enthusiastically before the judgment which time alone can pronounce. This method, now presented to notice, is supported by the experience of a year, and, consequently, has some claims to consideration.

You know, also, that the papers hitherto employed have made us seek a better preparation and more satisfactory results, consequently I believe we may satisfy the wants of the moment by the employment of the porcelain card (which never exhibits any defect) and in presenting it to the photographic world."—*Le Moniteur de la Photographie*.

PHOTOLITHOGRAPHY :

THE VARIED ACTION OF LIGHT UPON BITUMEN AND BICROMATES.—A NEW TRANSFER PROCESS.

BY JOSEPH LEWIS.

It is a fact I think not generally (if at all) known, that the principal sensitive substances at present in use to fix the offset of the photographic original on stone, viz., the bichromate of potash, with an organic medium, or the bitumens, effectually reverse or exchange their relative qualities under the effects of light. The bitumen is changed from a greasy, water-repelling substance, to that of a neutral insoluble material, having lost its property to repel water when applied to its surface. In this way I spread a solution of bitumen in lavender oil, or turpentine, upon a smooth stone, and when dry expose it for some hours under a transparent positive in good light. If we then wet the stone over with a little gum water and apply the printing ink roller, those portions unaltered by light will become charged with ink, while the altered bitumen, having lost its repellant power, remains wet, and the printing ink cannot adhere to a wet surface. Hence the early experimentalists failed to produce substantial effects by bitumen alone; they began at the wrong end—by washing away the *vital* printing surface and labouring hopelessly to charge with ink the faint brown impression left on the stone, whereas the solvent employed had washed away every particle of greasy principle. However, by this experiment we get a result which I have not reduced to a perfect success, for want of time to follow it up.

Now, in respect of the bichromate of potash and the organic substances when acted on by light, the effect is reversed; these, in their primitive state, are neutral in respect of moisture, but when decomposed by the light exhibit the qualities of a greasy substance, repelling water, and can be inked up as a lithographic stone. The bichromate, in combination with an organic medium, becomes, by the action of light, what has been termed insoluble; this, I think, is not correct nomenclature—there are many substances insoluble that will not attract printing ink, if moisture be present there is something more than insolubility imparted by the actinic influence; it appears to be converted into a *resinous* substance.

Reasoning upon results, I concluded to try the effect of a combination of these two opposite sensitive substances. I took one ounce of black asphaltum, a quarter of an ounce of suet, as much bicarbonate of soda as a shilling would take up, melted them in a pot, then added as much finely powdered bichromate as of soda, and a little fine black to colour. This mixture readily dissolves in turpentine, and in that state is brushed over a smooth card or paper surface; when dry, it should be pressed on a smooth wetted stone, to get a perfect surface. It is then ready for exposure under a transparent positive, or ordinary print, for some hours in good light. It is then to be submitted to the *capot* of turpentine for a few seconds (or the clean stone may be coated with a film of turpentine); the exposed surface is placed rapidly next the stone and submitted to the pressure as in the ordinary transferring, when, if the exposure has been properly timed, a perfectly sharp transfer will be found on the stone in *bona fide* transfer ink.

BY WHAT MEANS CAN THE ART OF PHOTOGRAPHY BECOME A SCIENCE?*

By the same means by which all arts become sciences; that is, by making systematic experiments, by recording results, and by combining these results so as to lead to infallible conclusions.

The chemical materials used in photography are numerous and are increasing daily; the experiments, therefore, must increase in the same proportion, otherwise results will remain without reasons. Every photographer can render important aid in this branch; he can make any amount of experiments; and, with a little system, he can make experiments that will be of great service to the department; and the photographic journals are always ready to record the results of such labours. From the accumulation of facts thus made, minds thoroughly educated in natural science will be enabled to make legitimate syntheses, that conduct to the causes and thus simplify the art.

Throughout the whole extent of the United States, as well as in several other countries, men are employed in different localities to record the direction in which the wind blows during the twenty-four hours of the day; the thermometric changes during the day; the variations in the height of the mercurial column during the same period; the diurnal, hebdomadal, mensural, annual, secular, and periodical variations of the magnetic needle; the fall of rain, snow, hail, &c.; the appearance of clouds, haloes, meteors, &c. These men are mere tools, experimenters, recorders of phenomena or facts; they draw no conclusions from what they see, and yet they are very *useful men*, like purveyors to the quartermaster, they accumulate heterogeneous materials which, systematically arranged, indicate definite causes and definite results.

In the course of time meteorology will become a fixed science, in which manifest laws will eventually prognosticate the change and direction of wind, the direction and spread of epidemics, the fall of rain, hail, or snow, and the change of temperature.

If photographers in like manner would organize themselves into a regular system of experimentation, there would be hopes of arriving at very beneficial results, and of drawing conclusions that can be derived from no other source.

But photographers say: What experiments shall we make?

* From *Humphrey's Journal*.

We will tell you some of the experiments that would be of great service.

An accurate table is needed of the solubility of the different salts used in photography in the different menstrua in which they may occur; for instance, we want to know exactly how much iodide of potassium can be dissolved in a given quantity of alcohol of a given strength; also of bromide of potassium in the same menstruum. The degree of solubility in alcohol of all the prominent photographic salts would thus form one table.

Another table would comprehend the solubility of the same materials in ether; a *third* that of the same substances in water; a *fourth* the solubility of the compound salts, such as *iodo-nitrate* of silver, &c., in a solution of nitrate of silver. A systematic view of the changes that occur in the different baths from the introduction of the different salts either on the collodion plate or the salted paper, would be of great practical value.

Photographer *A* may study the substance *nitro-glucose* in all its bearings, its composition and decomposition, its action on collodion, &c. This would be a very interesting addition to our photographic knowledge.

Photographer *B* will gratify the public by devoting himself to the study of the substance formed by the gelatinization of cotton in nitric acid, that is of gelatinous pyroxyline.

Photographer *C* can throw a quantity of collodion into distilled water and study thoroughly the precipitate both *gelatinous* and *fibrinous*. This will form the subject of two very interesting investigations.

Photographer *D* can experiment upon the solubility of pyroxyline in the different proportions of alcohol and ether.

Photographer *E* can take for his study the decompositions or reductions effected by the protosalts of iron on the collodion film after exposure. (Make no speculations; observe facts and note them well without any bias). This is a splendid subject for minute study.

Photographer *F* & Co. can make a comparative investigation of the action of light on chloride of silver, iodide of silver, asphaltum, bicromate of potassa and gelatine, &c., the persalts of iron, &c.—each one is a study of itself—let the experiments be directed to the ascertainment of the fact whether the action be *physical* or *chemical* or *both*.

Photographer *G* may take for his lesson or task the study of the reductions produced by gallic and pyrogallic acid on an exposed film.

Photographer *H* can by experiment try to find out by what principle of chemistry acids moderate the action of the reducing agents in the developing process.

Photographer *I* receives for his lesson the study of the reduction produced by the vapour of mercury on an exposed sensitized silver plate. Do not speculate—make experiments so as to derive some clue from the concatenation of their results.

Photographer *J* can investigate the (apparent) anomalousness in *this*, that a sensitized wet collodion plate when washed and exposed yields no picture by development, whereas the dry collodion plates are *thoroughly washed* and yield pictures.

Photographer *K* can study out the reason why an *acid gold* toning solution tones much more rapidly than an *alkaline gold* solution. He must show by experiment how it comes that the deposition of the gold in one case is so much more rapid than in the other. Compare this work with that of *H*.

Photographer *L* will gain a *prize* if he can distinctly diagnose the malady of the bath or the collodion which produces *PIN-HOLES*. Dust, iodo-nitrate of silver, acetate of silver, undissolved iodide of potassium, and bromide of potassium, &c., bear the onus of dreadful charges against them—find out, *by experiment and careful exploration* of the diseased ground, what is the true cause of the morbid manifestation—an infallible remedy will be the making of you.

Photographer *M* will study the anomalousness of results in reference to the introduction of formic acid into the developer. Claudet, Noyt, and others, assert that formic acid so introduced shortens the time of exposure; whereas Monckhoven and others do not obtain satisfactory results. Let the public know your experiments as soon as convenient, and what these experiments have determined.

Photographer *N* would interest the public by a careful set of experiments on the developing solution containing *tartaric acid* instead of acetic. This bath is said to produce sufficient intensity without redevelopment. The developer may be tried as follows:—

Water	4 ounces.
Sulphate of iron	1½ drachm.
Tartaric acid	18 grains.

A longer time of exposure is required with this developer than with the ordinary acetic acid iron developer. Try with less tartaric acid and report results, for the rest of your fraternity are on the pinnacle of expectation.

Photographer *O* has to investigate the peculiar conditions of an old and a new collodion, that will permit him to say what the causes are why the new collodion is more sensitive but produces less intensity than the old collodion, and *vice versa*.

Photographer *P* can experiment with the protosalts of iron, so as to determine in what way the protonitrate is superior to the protosulphate of iron as a quick developer; also in what way nitric acid or nitrate of silver is beneficial in the development of an ambrotype.

Photographer *Q*, if he is anything of a natural philosopher, will investigate the different degrees of intensity in actinism between the morning and the evening light, and between the spring and the autumn light.

Photographer *R* might commence a course of experiments on the action of polarized light on the sensitive films; these experiments may, perhaps, be of service to *Q*; I would advise these two philosophic photographers to enter into partnership and experiment together.

Photographer *S* may experiment in a totally new field. Let him combine nitrate of silver with collodion, albumen, gelatine, varnish, &c., and see if some new plan cannot be devised of obtaining sensitized films by inverting the proceedings, first saturating with silver and then sensitizing with the chlorides, iodides, and bromides. Something of this sort has already been attempted in France, and the results were published in *this journal*; exhaust the subject by experiment, and let us know what is to be expected of the change.

Photographer *T* may experiment on vision at long and short distances, and ascertain from facts why the eye is cognizant of a near and distant object co-simultaneously. To make these experiments you must be an anatomist and a physiologist, as well as a photographer and optician.

Photographer *U*, whether utopian or not, I would advise to ally himself with Niepce de St. Victor in the prosecution of the study of taking photographs of objects in natural colours. Certain colours can be photographed, but *not fixed*—the subject is worthy of investigation—it does not appear to be *utopian*—leave Becquerel's experiment and try fresh ground.

Photographer *V* would interest photographers if he could devise quick, easy, and practical methods of printing directly in the camera on prepared paper by development. This is a great desideratum, namely, to be enabled to take photographs on paper of a proper rich tone in the camera, as quickly as ambrotypes. This is not *utopian*, either. Experiment.

Photographer *W* may prosecute a course of experiments in celestial photography. His experiments are to be limited to the investigation of results to be obtained by repeated magnifying copies of the moon's disc taken on daguerreotypes. Is it not possible in this way to get a glimpse of the man of the moon? See to what extent copying and magnifying can be effected without the total annihilation of the object.

Photographer *X* may institute a course of experiments with the salts of chrome in gelatine, &c., to be used instead of collodion; see what can be accomplished in this way, and report at your leisure.

Photographer *Y* may conduct a systematic course of experiments on exposed plates or papers, by connecting them with either pole of a galvanic battery, either with or without metallic solutions in contact; see whether the actinic action is either increased, decreased, or unchanged by any of these arrangements, and study thoroughly the nature of the action, be it what it will.

Photographer *Z*, being the wisest man in the class, knowing all about the nutation of the earth's axis, the precession of the equinox, the secular disturbance of one planet upon another, being versed in the reason of a balloon's ascension, or a cloud's descension, of the rising of sap or the fall of gold, that is, being a man that knows how to put two and three together, or that two and three make five—*Z*, I say, will have for his task the collation of the reports of all his brethren preceding, and the deduction of causes.

DOUBLE PRINTING.

BY THE REV. S. MILLER.

[In the United States the process of double printing has recently been resuscitated, or rediscovered, with modifications. "Master Charley," an ingenious young amateur, son of the Rev. S. Miller, a contributor to *Humphrey's Journal*, has initiated the process. We now quote his father:—]

One day he came to my study with a face all radiant with smiles, and laid on my table a number of vignette portraits as the results of his new experiment. One was the portrait of a lady surrounded with a wreath of flowers. Another had a landscape as a background. Another a battle field for its foreground, himself looking out on the scene from the background as if he had been the general commanding. Another placed a lady friend in company with the newly-married Princess of Wales and her bridesmaids. Another made a gentleman figure on a valentine in the midst of all sorts of hard and soft hearts. Another gentleman was introduced to a wedding party, and yet another was made a spectator at a French bee dance.

The family were called in to see the new pictures. It afforded one of those pleasures we often enjoy as a family circle of amateurs. All were delighted, and Charley was duly complimented by his sisters. No one could guess how the thing could be done, and they made him sit down and tell how he did it. It was all plain and simple enough when explained. They call them the Carlotypes, to which the artist makes no objection, being conscious that the process by which he produced them was the result of his own unaided experiments.

His double printing process is entirely different from that given by Dornbach, whose articles he had never seen; and the pictures themselves are of a different style. The process is very simple, and yet it possesses a feature that would puzzle some older heads to understand how it is done, without being explained. He can print, for instance, a dozen of these pictures, each one with a different background in precisely the same time required to print an equal number of ordinary pictures; thus affording any variety of chemical backgrounds without additional time and labour in the manipulation beyond that required in the single process.

If the trouble connected with the production of these backgrounds is the reason why the subject has not received more attention from practical operators, that reason no longer exists as far as vignette portraits are concerned, to which the present experiment has been so far confined. There is room left accordingly for still further improvements, in order to produce like results with standing figures with the same facility.

May not the time come when double and even triple printing will be as common and as profitably applied in the photographic art as it is in the art of printing, and with like pleasing and popular results?

The carlotypes, as our young amateurs persist in calling them, are produced by a double printing process, by which vignette or bust pictures, with any variety of backgrounds, are printed without requiring any additional time to that which is necessary to produce ordinary pictures. A dozen copies from the same negative, each with a different background, can be printed in precisely the same time that an equal number of ordinary copies are produced. I will describe the manipulation for the benefit of the lovers of variety.

1. Make a tasteful selection of appropriate objects for your chemical backgrounds. The sources from which these can be selected are unlimited. Every object in nature and art can be used for the purpose, and be represented in connection with portraiture. The backgrounds most easily obtained are those copied from prints and other portable works of art, from which alone a fine selection can be made.

2. Having made your selection, take a well defined negative of each. In doing so, bring that portion of the view which is to be occupied by the portrait, on the centre of the glass. These negative backgrounds are to be considered as part of your stock, being of permanent use if well taken care of. They should be well varnished and be kept in a separate box.

3. Cut out as many ovals from yellow paper as there are negatives, the size of a sixteenth or ninth part, or any other size or form to suit the design and size of your negative. The yellow paper used for letter envelopes will answer the purpose. Mount the ovals on the back of your negatives on the centre of your glass or place which the portrait is to occupy. They serve the double purpose to make room for the portrait and to pro-

tect it in the process of printing. The reason why they are pasted on the back of the negative and not on the collodion side is, for the double reason, to blend their outlines when desirable, and to enable you to remove them when so desired, without injury to the negative.

4. Cut out an equal number of ovals from white tissue paper a little larger than the former, and mount them on the yellow ovals, allowing them to extend over about an eighth of an inch all round. This serves to complete the blending of the outlines referred to; but is to be omitted when the outlines are to be sharply defined. Your negative or chemical backgrounds are now ready for use.

5. The next thing is the printing process. We will suppose you desire to print a dozen copies from a single negative, each to have a different background, and to produce them in the same time required for an equal number of ordinary vignette pictures. Very well. Have your paper ready and your portrait negative at hand. Place a prepared sheet of paper under the negative, and put it in a vignette printing frame. One on which the glass is fastened by means of spring cloth pins will do. Then place another sheet under a negative background, and put it in a common printing frame. Expose them simultaneously to the action of sunlight. When both are sufficiently printed, carry the frames on a table and open them. Take out the negative background and put another in its place. Then transpose the prints; that is, place the printed portrait in the common printing frame and the printed background in the vignette frame, adjusting them properly on the negatives, so that the portraits will be protected by the ovals. Expose them again to the action of light, when sufficiently printed, take out the copies, and repeat the operation; using a different negative background at each exposure.

You will note that whilst the portraits were printing, the backgrounds were printing likewise; so that by the time the former were printed, the latter were printed as well. No loss of time was therefore occasioned in producing the double impressions. The process is as simple as it is curious and pleasing in its results, and affords room for a pleasant variety of experiments for the amateur, to say nothing of the practical purposes to which it may be applied. The principle can be carried out still further, and with a triple process, pictures can be produced with three distinct impressions in the same time. As a contribution to photographic curiosities, I may at some future time describe the manipulation, and report results.

If this style of pictures could be made to find favour with the public, it would pay an enterprising publisher to get up a variety of beautiful designs, of a general and specific character, with the proper sized oval or square openings, expressly engraved for the purpose in the best style of the art, as patterns for chemical backgrounds. By this means exquisitely beautiful results would be produced, which would hardly fail to meet with favour by the public; thus introducing a new feature in practical photography, by bringing into its service the art of engraving as it has already done that of painting.

FALSE CLAIMS IN REGARD TO MEDALS OF THE INTERNATIONAL EXHIBITION.

WE have just received the report of a committee of gentlemen appointed by a meeting of medal holders, for the purpose of securing some protection to medallists against various fraudulent claims which had been put forth, for trade purposes, in reference to the awards of the jurors in the International Exhibition. It appears that in some instances the honours of the medallists have been claimed in advertisements by persons having no right to them whatever; in others medals awarded for one thing have been claimed for another; and various similar frauds have been committed. The existing law failing to provide a remedy, a short bill was prepared, which received the royal assent within eight days of its first reading in the House. It is entitled "The Exhibitions' Medals Act, 1863," and we extract its principal provisions for the benefit of those interested:—

Whereas it is expedient to prevent false representations with respect to grants of medals and certificates by the Commissioners for the Exhibition of 1851, and the Commissioners for the Exhibition of 1862: be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the

Lords spiritual and temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. If any trader commits any of the offences following; that is to say,

- (1) Falsely represents that he has obtained a medal or certificate from the Exhibition Commissioners;
- (2) Falsely represents that any other trader has obtained a medal or certificate from the Exhibition Commissioners;
- (3) Falsely represents that any article sold or exposed for sale has been made by, or by any process invented by, a person who has obtained in respect of such article or process a medal or certificate from the Exhibition Commissioners;

He shall incur the following penalties; that is to say,

- (1) For the first offence he shall forfeit to Her Majesty a sum not exceeding five pounds.
- (2) For any subsequent offence he shall forfeit to her Majesty a sum not exceeding twenty pounds, or be imprisoned for a period not exceeding six months.

2. In proceedings under this Act it shall not be necessary to prove that any person has sustained damage by the false representations of the defendant. In proceedings under this Act the defendant shall be deemed, until he has proved the contrary, to have known the falsehood of any representation made by him that has been proved to be false. It shall not be necessary in any proceedings under this Act to set out any copy or facsimile of any medal or certificate.

4. Offences under this Act may be prosecuted summarily in England and Ireland before two justices. In Scotland, an offence against this Act may be prosecuted summarily at the instance of the procurator fiscal before any sheriff or before any two justices of the county, or before the magistrates or any police magistrate of the burgh in which the offence was committed.

5. No provision of this Act shall take away, diminish, or prejudicially affect any suit, process, proceeding, right, or remedy which any person may be entitled to at law, in equity, or otherwise; nor exempt or excuse any person from answering or making discovery upon examination as a witness, or upon interrogatories or otherwise, in any suit or other civil proceeding: provided always, that no evidence, statement, or discovery which any person shall be compelled to give or make shall be admissible in evidence against such person in support of any indictment for a misdemeanour at common law or otherwise, or of any proceeding under the provisions of this Act.

HOW TO CLEAN GLASS PLATES.*

An excellent starting point of success is to obtain a nice clean plate. A good operator knows that unless his glass is clean he has no security for obtaining a perfect picture. Many different methods have been given for effecting this apparently simple object, but the plan that seems to be perfection with one person, is declared to be useless by another.

New glass plates are always best; old plates many times used, or that have laid about with their dirty surfaces, or that have been varnished, are always to be regarded with suspicion. It is very doubtful if there is any saving in using a plate that has once been varnished. A truly economical photographer will have the courage to use the hammer to lots of his old glass rather than risk his materials, his time, and his temper on plates which may give only dirty pictures. The chemicals, especially the protosulphate of iron and cyanide of potassium, seems to act on the surface of the glass, so that after much using no amount of friction with acids or alkalis will prevent smears, marks, *ghosts*, comets, rockets, and other abominations. Now glass works well with very little cleaning. Patent plate is always the best; but for small sizes, up to 5 by 4, "flatted crown" will do, and "polished sheet" for larger sizes. It is a good plan, if there be a doubt whether the glass plates are flat enough, to put them into the printing frame, and apply quite as much pressure as will occur in printing, for few

things are more mortifying than to break a negative through using glass not flat.

To prevent cutting the fingers and tearing the cloths, the glasses should have their sharp edges and corners taken off, and to make the collodion adhere well at the edges, it is better if they are roughened a quarter of an inch all round. Sand paper, emery cloth, sandstone, or a little grooved instrument made of corundum and sold for the purpose at most photographic dealers, may be used.

New glasses may be simply washed under the tap with plenty of water, and dried on clean cloths. When quite dry, place the glass in a plate-cleaning holder, and pour on a few drops of pure alcohol; rub this well over the plate on both sides with a tuft of cotton wool. With a second tuft rub off the alcohol, and with a third one polish the plate. This will be found a safe and expeditious method of cleaning plates. The last tuft of cotton should be kept quite clean and dry, so as to leave the plate without lines or smears. If the reader has much trouble with dirty glasses, he is strongly recommended to try "Werge's Plate Cleaning Solution." The writer has used it for years, and is never troubled with dirty plates, and he feels he is doing his readers a service in calling their attention to this very useful preparation.

Every dark room should have a large dish provided, half filled with clean water, into which all spoiled plates should be immersed, so that the collodion film should not dry on the plate. By this plan much time will be saved in cleaning the glasses, and the plates will be kept in better order. The plates should not be left to lie in this water any longer than possible, and the water should be frequently changed. The fragments of collodion films should be added to the pan in which the silver residues are kept, as they all help to swell the amount.

The above simple means may not be satisfactory to some persons for cleaning their glasses, therefore the following plate-cleaning solutions are given, culled from a variety of sources:—

GLASS PLATE CLEANING SOLUTIONS.

No. 1. (Mr. Hardwich).

Make a cream of tripoli powder and spirits of wine, add a little ammonia; dip a tuft of cotton in the above, and rub the glasses for a few minutes, rinse them well in plain water, and dry on a clean cloth kept for the purpose, which cloth should be washed in pure water, or water containing a little common washing soda, but not with soap and water. Polish the plates with an old silk handkerchief, or clean chamois leather.

No. 2. (Mr. Hardwich).

Liquor potassæ	1 ounce.
Water	4 "

Wet the glasses well on both sides with the above, using a cylindrical roll of flannel to protect the fingers; allow them to stand while several are so treated. Wash them well, dry, and polish.

No. 3. (Mr. Lake Price).

Wash the plate with abundance of clean water running from a tap, wipe with old linen cloths kept scrupulously clean, and retained for the purpose. Polish with clean chamois leather, or old silk. If the plates are greasy, give them a preliminary wash in warm soda water; if they have been previously used, let them lie for six hours in a strong solution of caustic potash with thin slips of firewood between them to ensure the surface being acted on. When cleaning the plates, wear a pair of white cotton gloves to prevent the plate or the cloths being contaminated with the perspiration from the hands.

No. 4. (Mr. Sutton).

Rub the glass plate on both sides with a piece of flannel dipped in a thick mixture of whiting and water; wash off the whiting thoroughly, and put the plate in water acidified with nitric acid; wash again, and wipe dry with a clean

* By permission, from Hughes's "Principles and Practice of Photography." New Edition.

cloth kept for the purpose, and which must never be washed with soap. Before using, polish with a silk handkerchief.

No. 5. (Mr. Thomas).

Prepared tripoli	2 ounces.
Water	3½ "
Spirits of wine	4 "
Solution of caustic potash	½ "

With a tuft of cotton wool rub the plate well with the above mixture, wash the mixture off under the tap with another tuft, being careful to get the tripoli from the roughened edges. Let the plate remain in a deep dish of water till six plates are thus treated; take them out singly, wiping the edges with a tuft of cotton, and pass them through a dish of distilled water. Dry them with cloths washed without soap. Polish with chamois leather, and finish with a silk handkerchief.

No. 6. (Mr. Crookes).

Place two handfuls of common salt in a jug, and pour a pint of boiling water over it. Stir for some time, allow to get cold, and filter. Mix together equal parts of fine rotten stone and tripoli, and add about a teaspoonful to every six ounces of the above saturated solution of common salt. To use, shake the bottle well, and smear a little of the mixture over the plate with a rag. Now clean it well off by briskly rubbing with a clean cloth, and give the last polish in the usual manner. The crystallization of salt which takes place on the surface of the plate when the mixture is smeared over seems to loosen the dirt from the surface in a remarkable manner, and the after friction with the cloth brings away all impurities. Care must be taken that no salt is left on the edges of the plate, or it will decompose the bath.

In relation to the above, Mr. Crookes says, "That if the receipt be properly used, a failure from the employment of dirty glasses may be looked upon as a thing of the past."

No. 7. (Mr. W. Miers).

Water	1 ounce.
Hydrochloric acid	2 drachms.
Iodine	a few grains

Rub the plates over with a pad of cloth saturated with the above liquid, use a circular motion, and polish as well.

No. 8. (Mr. G. Wharton Simpson).

Nitric acid	1 drachm.
Alcohol	1 ounce.

Tripoli, sufficient to make a creamy paste.

Rub the plates well on both sides with the above paste, and set them aside to dry. In this condition they may be stored away; when required for use, rub the tripoli off with a fine clean cloth, and polish with a clean chamois leather.

To Clean Plates that have been Varnished.

Soak the plates in a saturated solution of common washing soda, and allow them to remain until the film comes off without any friction. If the solution is made hot, a few minutes will be sufficient; but cold, they usually require from 24 to 48 hours soaking. When the film leaves the glass freely, wash it well under the tap, and immerse it in weak nitric acid (water 5 ounces, nitric acid 1 ounce), for a short time. Wash well again, dry, and treat it as a new glass.

As the varnished side can never be much depended on, it is a good plan to mark the unvarnished side with a diamond before cleaning, and to use the marked side for putting the next collodion film upon.

Photographic Notes and Queries.

WANT OF INTENSITY IN DRY WEATHER.

DEAR SIR,—Many have complained recently of the want of intensity in negatives, and the dryness of the atmosphere has

been generally suggested as the cause. Allow me to state how I have overcome the difficulty (for it would not be convenient for every photographer to adopt Mr. Noel Fitch's plan, viz., to water the floor of the studio.) I simply coat the plate, and immerse it in bath, as quickly as possible. Hoping this hint will sufficiently explain how the dryness of the atmosphere affects the plate, and help others out of the difficulty.—I remain, yours truly,
J. BURGESS.

Talk in the Studio.

THE WATT PHOTOGRAPHS.—We understand that Mr. Smith, of the Patent Museum, is progressing satisfactorily with his researches into the history of the photographs taken during the last century, and hopes shortly to present indisputable evidence of the claims already made regarding them. A paragraph in a recent number of the *Bulletin* of the French Society strikingly illustrates the impolicy of the discussion on the subject, upon imperfect data, at a meeting of the Photographic Society of London, and which we personally deprecated at the time. The discussion is regarded in the French journal as upon the two pictures, resembling daguerreotypes, of Bolton's house before and after its alteration in 1791, and as having seriously decided that the pictures were not photographs at all. After rehearsing the question generally, the paragraph proceeds:—"A serious discussion at the Photographic Society of London, seems not to have left any doubt upon the origin of the images; they have not been produced by the direct action of light; they are simply pictures painted in the ordinary manner, perhaps designed in the camera obscura, and it is entirely to Niepce and Daguerre that the honour of discovering photography belongs." Englishmen have not been grudging hitherto in their tributes of honour to Niepce and Daguerre; it is simply a question of historic truth which now remains to be solved. But is it not somewhat odd that our neighbours forget that photography, as discovered by the savans their name has now ceased to be practised, and that the photography of the present day, on collodion and paper, was discovered by Englishmen?

PHOTOGRAPHY AT WIMBLEDON.—Mr. Ernest Edwards has just published some photographs of the recent rifle matches at Wimbledon, which volunteers generally will be glad to possess. We have before us two instantaneous pictures, panoramic in form, measuring about 10 in. by 6 in. One consists of Mr. E. Ross—himself, we believe, a photographer—shooting at one thousand yards, seated; and the other of Mr. Farquharson, shooting at the same distance, extended at full length on the ground, after his peculiar fashion. The pictures are exceedingly good, being delicate, soft, and well defined, except in the case of a few figures, which, notwithstanding the rapidity of the exposure, have moved a little.

PHOTOGRAPHY IN THE WITNESS BOX.—A singular use of a photograph was made in a recent trial in the Central Criminal Court. The charge upon which the prisoner, a lad of seventeen, was tried, occurred two years ago, and a photograph of him taken at that time was produced to prove that he had altered so much since that time that it was impossible to swear to his identity now. The jury, however, regarded it as a good likeness of him as he stood before them.

PHOTOGRAPHY IN THREE LESSONS.—This is the title of a terse little brochure just issued by Mr. Solomon. Its purpose is best explained by an extract from the introduction:—"This is entirely a book for beginners. It does not deal with the history of photography, nor its theoretical principles, nor its manufacturing chemistry. The beginner will purchase his apparatus and materials ready made; mix his preparations as we shall direct, and use them as we shall instruct him, his sole object at present being to take pictures. When he has accomplished this he will begin to inquire upon what principles this art is based, and make some practical experiments in its chemistry. But he will begin by learning the practice. A man learns to talk before he studies grammar." The three lessons consist of instructions for producing collodion positives, for producing collodion negatives, and for producing paperprints. The style is short, sharp, and decisive, and whilst there does not appear a superfluous word, the instructions are clear and explicit. We do not doubt that a person of average intelligence might take the book in hand and without other tuition produce pho-

tographs. The book finishes with a piece of excellent advice: the student having mastered the instructions before him is recommended to read the photographic periodicals and join a photographic society.

ARCHITECTURAL STEREOGRAPHS.—We have received from Messrs. J. and J. Dutton, of Bath, some exceedingly fine stereoscopic views, chiefly church interiors in Bristol and Bath. There is a very fine view of St. Augustine's Gate, Bristol, which is an unusually elaborate specimen of Norman architecture. There are also views of the interiors of Bath Abbey, Bristol Cathedral, and the church of St. Mary Redcliffe which are known to archaeologists as presenting fine examples of the early English, the Perpendicular, and Decorated styles of architecture.

TRANSFERS FROM ENAMEL PAPER.—We have just received from the Hon. Nassau Jocelyn, Secretary to the British Embassy at Berlin, some exceedingly beautiful specimens of the new process of transferring the film of albumen containing a photographic image, from the paper on to enamel glass, or other surface, for ornamental purposes, together with hints as to the method of manipulation. We have also received from Messrs. Harvey, Reynolds, and Fowler, some samples of M. Beyrich's paper, prepared for this work. We hope shortly to enter at greater length into the subject.

MR. PARKINSON'S LIME TONING.—We have recently received a letter from Mr. Parkinson on this subject, in which he expresses a conviction that if "Cha-meal-ion" had used as much ability and intelligence in applying the lime-toning formulæ as in writing his amusing letter, he could not have failed to secure success. He proceeds to say:—"Toning with me these last six months has been a pleasure instead of a trouble, and I am sure that the lime toning will eventually become universal, more especially as I have discovered, within this last week, that it can be used with that invaluable aid, *acetate of soda*. For the information of "Waxy," my paper is bought at Angouleme, gold at Paris, and lately I have changed my *fournisseur*, but with equally good results. The day before yesterday M. Disderi, called on me, and although very busy, I gave him a pose and a poser with the rapidity with which I work in my new atelier, and outside it is quicker than quick, as you will see by the enclosed equestrian carte. He was so pleased with the lens that he has taken Dallmeyer's address, and is going to write to him for one. I also took a *carte de visite* of Disderi, which I enclose." Mr. Parkinson proceeds to promise us some further remarks on his toning experiments shortly, and concludes with a challenge, as follows:—"Should 'Cha-meal-ion' happen to be a sporting man, I will take a series of pictures against his old hypo and gold, by my chloride of gold and lime processes, for £20 a side, and come to England to do it; any six *first photographers* to be the judges."

To Correspondents.

A MUFF.—A bath treated with carbonate of soda, as you describe, will, in some conditions, hold a trace of carbonate of silver in solution. When you add acetic acid to this you form acetate of silver, which, although conducive to density of image, and occasionally of advantage when a pyro-gallic acid developer is used, is not, in our experience, suitable for iron development, often giving insensitiveness and dirty plates. After neutralizing and sunning your bath, it is better to add nitric acid than acetic acid. If your bath reddens blue litmus paper and turn reddened litmus paper blue, there must be some impurity in your material or manipulation. A bath cannot be acid and alkaline at the same time. Possibly you tried it with the red litmus paper in the light, and you mistake the darkening by light for becoming blue. It frequently happens a dull light and short exposure reveal any fogging tendencies in a bath much more palpably than full exposure in bright light. The red deposit on the shadows whilst intensifying may often be prevented by an increased proportion of citric acid. The iodine solution you use for the purpose is much too strong; one grain to an ounce of water will make a solution amply strong enough. Try intensifying with iron 5 grains, and citric acid 5 grains, to which add a little silver without acid.

TYRO-TANNIN.—The difficulty you describe is a novel one; we have neither heard nor met with it before. We can perceive nothing in your material or manipulation to cause the small projections or bubbles you describe. We have before heard of the final spots which you state these bubbles or projections result in, but have not heard of the phenomenon being observable on the excited plate. From one hint you drop, namely, that an excited plate showing these projections when taken into daylight becomes covered with blue spots, seems to point to excess of bromide as the cause. Bromide of silver is readily reduced by light, and becomes of a bluish grey colour when so reduced. These spots then may possibly arise from excess of bromide in the collodion, or from the bath having become supersaturated with it; the latter most probably, and if so, sunning the bath would be the remedy. We will submit your letter how-

ever, to Major Russell, whose recent extensive experiments may enable him to throw some light upon the matter.

J. W. F.—The print enclosed has a very odd appearance, and from a mere superficial inspection it would be difficult to determine the cause. Examination by transmitted light, however, speedily suggests the source of the trouble. Your printer has floated the paper on the bath albumen side uppermost. By this means the bulk of the silver is in the body of the paper, and hence the image is there also, and is scarcely visible on the surface. By transmitted light this is very apparent, as the print is an excellent transparency. This is further proved by touching the back of the paper with the tongue, which at once detects the plentiful presence of free nitrate, whereas on the albumenized side it is scarcely perceptible.

J. D.—In working dry plates without preservative much seems to depend upon the collodion. Those samples which are old and slightly decomposed, or which are made from cotton with somewhat of the organic character, seem to answer best. But you can only get at the matter by experiment, as to which especial sample will answer. Plates so prepared are more sensitive than tannin, but less certain.

J. LEE informs us that he has used the lime toning formula we gave in No. 257 with great success. He asks, if Beaufort's concentrated chloride of lime may be used in a similar formula? We have not tried the preparation in question; but apprehend that, if used, must be in much smaller proportion than in using the common article from the oil-shops; the proper amount being ascertained by experiment.

J. C.—The fog on the deep shadows during intensifying with proto is not uncommon in hot weather. In our last volume the subject is very fully treated, and also in our *ALMANAC* for the present year. It proceeds from a variety of causes, and may be got rid of by different remedies. The simplest is to use a larger proportion of citric acid in the intensifying solution. The most effectual method is to have a solution containing 1 grain of iodine and 2 of iodide of potassium in an ounce of water; and after washing away the iron, pour the solution over the plate; then expose for a few seconds to the light, wash off, and proceed to intensify. With negatives in which, despite of precautions, the defect has arisen, it may sometimes be removed by the application of a weak solution of iodo-cyanide of potassium. This requires great care not to injure the half-tones. Another method is to pour a weak solution of bichloride of mercury over the plate, which, without much affecting the general character of the negative, will turn the red foggy deposit white, and thus render it of little consequence in printing.

A DRY PLATE.—The introduction of an organic salt into the silver bath not unfrequently produces the reduction you describe. A skilful and eminent photographer recently described to us just such a result with a bath made after Mr. Bartholomew's formula, but he added that its working qualities did not appear to be impaired.

AN AMATEUR.—You speak of developing with formic acid, as used by Mr. Claudet, and you add that your bath is nearly neutral. Now, if you have read the description of Mr. Claudet's method with any care you will have ascertained that he places great stress upon having the bath freely acidified with nitric acid. We can only suggest to you the importance in adopting any specific formula of working it out accurately in all its parts. Want of detail is most likely to occur from under-exposure, or the use of too much old potassium iodized collodion.

CHUCK.—It is probable that your bath has contained a large excess of acid, and requires still more carbonate of soda to neutralize it. You should add the soda until there is a slight permanent precipitate, and then expose the solution to sunlight. 2. We shall be glad to see the specimen of paper to which you refer. 3. Mr. Poncey is quite prepared, we believe, to supply his prepared paper to amateurs.

J. H. McALLAN.—Of course, your room would be better if the chimney were removed, but it is not imperative. Paint or paper the interior with a warm, light, neutral tint. Double sets of blinds, one dark blue, the other white, and on both sides. A good half-plate lens will answer for card pictures, but we fear that more than sixteen feet length will be required to enable you to use a lens of the usual focal length belonging to half-plate lenses.

SOLAR.—We are not aware of any house keeping mirrors and condensers for the solar camera. Probably Mr. Atkinson, of Liverpool, could supply them, and, possibly, London dealers would supply them to order. We remember seeing a condenser of French manufacture for sale at McMillan's, Fleet Street. The price would depend on the size; probably, for an eight-inch condenser, about 30s., if of French manufacture.

A CASE OF NEED.—We have to acknowledge from H., postage stamps amounting to 2s. 6d., and we are also glad to announce that an important contribution of apparatus has been made by "One of the Brothers of the Art," who desires to be anonymous.

THE MARSEILLES PRIZE.—We have no information as to how sensitive plates will reach Marseilles without being examined by the Custom House officers. We imagine, if duly and fully described outside, it is possible they might pass unopened. But we will make some inquiry.

W. L. N.—Press of engagements and the unfavourable weather have prevented us from giving the collodion a trial as yet. Several Correspondents in our next.

SULPHO-CYANIDE OF AMMONIUM AT A LOW PRICE.

THE results of some experiments a few months ago, limited, it is true, in number, but carefully conducted and very conclusive, led us to the conviction that if this salt could be manufactured at a reasonable price it would take the place of hyposulphite of soda as a fixing agent, and at once free the photographer from many of the evils which attend its use supplying the place by one equally efficient, more stable, not readily liberating sulphuretted compounds, nor spoiling prints by the formation of an insoluble and unstable salt in case of under-fixation. A general impression to this effect seemed to prevail in most cases where the sulpho-cyanides were tried. The price was, however, an insuperable difficulty. It was impossible to employ, commercially, for fixing photographs, a salt which cost four shillings an ounce. That objection has, however, ceased to exist.

We have just received from M. Meynier, of Marscilles, the gentleman to whom the original suggestion of the new fixing salt is due, two large bottles containing a fine sample of sulpho-cyanide of ammonium. This salt, which is very perfect, and in fine, clean, colourless crystals, he is now manufacturing and selling at the price of three francs per kilogramme. This, in English money, is half a crown for two pounds and a fraction under a quarter, or about one shilling and three-halfpence per pound.

The question of price, even now, may cease to be a consideration; and M. Meynier states that if the consumption becomes general he has no doubt of being able to manufacture it at the price of hyposulphite of soda.

We have tried the sulpho-cyanide of M. Meynier for fixing, using the proportion we employed on a former occasion, one part in three of water, which is a much greater strength than that originally recommended by M. Meynier. The results varied very slightly from those we obtained before, but the differences might possibly be due to the character of the paper, &c. The solution seemed more energetic, reducing the prints both in colour and depth to a greater extent than we before found it. Let us not be misunderstood, however; the reduction was not greater even now than with hyposulphite of soda. The colour, a deep purple, obtained in the toning bath, simply became a purple brown, or rich warm sepia tint. In some cases the tint was peculiarly rosy purple in the shadows and pink in the half-tones. The whites were perfectly pure, exhibiting no trace of yellow.

M. Meynier informs us that he finds the use of a bath containing sulpho-cyanide of ammonium and chloride of gold very satisfactory for toning. It is composed as follows:

Sulpho-cyanide of ammonium	...	6 grammes.*
Chloride of gold	...	1 gramme.
Water	...	1 litre.

* A gramme is about 15½ grains, and a litre 35 ounces.

The print immersed in the bath acquires, first, a lilac tint, and passes through violet to black, if left in the bath a sufficient length of time. The solution will be found to have an acid reaction, and, if a fine black or violet tone be desired, it should be neutralized by the addition of a few drops of ammonia, or of a solution of carbonate of soda. It is then to be fixed in another bath of sulpho-cyanide of ammonium alone, M. Meynier using, we believe, one drachm to an ounce of water.

Regarding the permanency of prints so fixed, there is every reason to entertain the hope that they will be more stable than those treated with hyposulphite of soda. It is barely six months since we commenced our experiments. The pictures then fixed do not, however, show the slightest sign of change. M. Meynier informs us that he has used this salt for twelve months, without the slightest trace of yellow or fading having been found in any of the prints, whilst some fixed at the same time in hyposulphite of soda, show unmistakable traces of yellow in the lights. He adds, he is satisfied that as soon as photographers discover all the advantages of sulpho-cyanide of ammonium, hyposulphite of soda will be banished from their establishments.

We have not yet had time to try the method of toning suggested by M. Meynier; but we can readily conceive it to be desirable, if the new salt be used for fixing. We hope to try it shortly, and report further as to the results.

MAJOR RUSSELL'S RECENT MODIFICATIONS OF THE TANNIN PROCESS.*

WE resume our examination of the excellent manual of Major Russell.

THE TANNIN SOLUTION.—The original fifteen-grain solution of tannin has ceased to be regarded in any degree as of a standard strength. Major Russell finds in his later experiments that the strength may vary with advantage from two grains to thirty grains to the ounce, according to the subject. A strong solution gives great vigour and richness of tone; but slightly impairs sensitiveness. In some cases it has another singular effect. If the subject have much contrast and be very strongly lighted, a plate prepared with a strong tannin solution and iodized collodion gives a blurring of the lights which appear to encroach on the shadows. In such cases the use of a weaker solution of tannin is found to be a remedy. For well lighted landscapes a two-grain solution is recommended. The best proportion of tannin is to be decided by circumstances; as a rule, the feebler the image on the ground glass, the stronger should be the solution of tannin. "In no other process," Major Russell adds, "can the vigour and intensity of the picture be so easily regulated as in this, by varying the strength of the tannin solution." When the collodion contains bromide only, a larger amount of tannin may always be used with advantage, without any

* Continued from page 401

fear of producing the blurring referred to. Eight grains to the ounce may be used in such case with safety.

Regarding the quality of various samples of tannin it is observed that although much difference as to the degree of solubility is found in various commercial samples, in result the action is tolerably uniform. The chief difference in the various samples seems to consist in the amount of resinous matter they contain, which requires filtering out before use.

Two samples of tannin were forwarded by Mr. Williams, of Liverpool, one of which he found to yield less sensitiveness than the other, and likewise inferior results. Both samples were dissolved in water mixed with a little alcohol, but were not tried for several months: at the end of that time, on being examined, both solutions were clear and in good condition. The worse had thrown down a rather copious flocculent deposit, the better a slight deposit which adhered to the bottom of the phial. Several plates were prepared with each and tried carefully in pairs. Scarcely any difference appeared in the results; the worse sample seemed generally to have a slight advantage in sensitiveness, and there was a little difference in the colour of the images. It would appear from this that some samples of tannin contain an injurious impurity which is precipitated by keeping in solution.

For very full information on the preparation, keeping, and mode of applying the tannin solution, we refer our readers to the work itself, which deals very minutely with this subject.

EXPOSURE.—The question of exposure has always been regarded as a very important one in regard to all dry processes. Unless something like the rapidity of the wet collodion process could be secured it is doubtful whether what may be termed a semi-rapid process possesses any essential advantages over those which are known to be slow. If the exposure need to be one minute, for instance, it might as well be five. In some instances better. For if any object move across the field of view at a moderate pace during a five minutes' exposure, it will probably leave no impression on the plate; but if the exposure were one minute, the plate being five times more sensitive it is very probable a blurred mark, spoiling the picture, would be left by such a moving object. It is not the less, however, an important object to increase the capabilities of rapidity in dry plates, and Major Russell informs us that he has made great advances in this direction. On this subject he remarks as follows:—

With regard to the time of exposure, much difference will be found in the sensitiveness of the plates, according to the mode of preparation. The principal causes of insensitiveness have been already given; they are the use of a simply iodized collodion, or of an old sample, or the presence of more acid in the bath or collodion than is required to keep the pictures bright. Should two, or all of these unfavourable conditions be combined, the insensitiveness will be very great. The use of an alkaline, or impure bath, with a nearly or quite colourless collodion, will also produce insensitiveness to half-tones as well as fogging.

The writer has prepared plates by the method given in the preceding pages more sensitive than those he can produce by any other dry process with which he is acquainted, consistently with obtaining vigour and brightness, and he believes that this process will be found to give brilliant and vigorous results, combined with softness and good half-tones, with greater facility and certainty than any other process when the subject is feebly lighted; and if the tannin solution is of suitable strength no difficulty will probably be found with any kind of subject, especially when simply bromized collodion is used for such as are strongly lighted and present great contrast.

DEVELOPMENT.—If the plates have not received a preliminary coating it is better, before development, to paint round the edges with a solution of india-rubber. In moistening the film, Major Russell recommends the adoption of the suggestion made in our pages by Mr. Bartholomew, as to the use of dilute alcohol instead of water. He says:—

The use of diluted alcohol* instead of water to moisten the plate for development is a very great improvement in several ways; it prevents the expansion and consequent wrinkling and

* The writer is indebted to a correspondent of the PHOTOGRAPHIC NEWS for a knowledge of the fact that alcohol mixed with the water used to moisten will prevent expansion and loosening of the film.

loosening of the film to so great an extent that it is generally easy to work in this way without any previous coating, if the film of collodion is not very thick. When gelatine is used this mode of treatment enables us to work with a thinner solution, which is more easily applied, and less likely to permeate the collodion injuriously: it makes the feeble adhesion of a thin coat of india-rubber usually sufficient; but by far the most important advantage is this:—The alcohol, by its superior penetrating power, will restore the porous condition of the film when a very weak solution of tannin has been used, and even when the tannin has been washed off immediately after being applied; whereas, if the plate is moistened with water alone, the mechanical effect of a much larger amount of tannin is required, or the development will be very feeble; the chemical effect is then so great that, when the collodion contains iodide, it frequently renders the plate incapable of producing the best quality of negative with the kind of subject for which dry plates are most frequently used—landscapes with sky and dark objects.

In reference to the developer for general use, Major Russell adheres to the principle he originally published, keeping a stock of strong pyrogallie acid solution, and of citro-nitrate of silver, diluting and mixing these as occasion may suggest, as we have before described, and as he, in the edition before us, minutely details. Referring to the method of using pyrogallie acid solution alone for bringing out the image as first suggested by Mr. Wardley for collodio-albumin plates, Major Russell says:—

With some kinds of collodion the development may be started with pyrogallie alone; but with others, which have but little organic reaction, nothing can be brought out in this way. In some cases the pyrogallie seems actually to weaken the invisible impression, making the image, when brought out by the addition of silver, to appear less exposed than if the developer had contained a little silver from the first; when the pyrogallie is applied alone at first, however, the mixed developer usually keeps very clean. When a plate is under-exposed, a slight advantage may be gained by using the first portion of silver in the developer without acid: only a very slight trace can be used in this way. For this purpose, a drop or two of a ten-grain solution of nitrate may be diluted with half-an-ounce of distilled water, and a drop or two of this dilute solution mixed with the pyrogallie for a stereoscopic plate before applying for the first time to the film, the writer has not tested this plan sufficiently to be able to recommend it with confidence.

The use of formic acid in the developer appears to be attended with some advantages, both as regards shortening the exposure and rendering detail. The author observes:—

If formic acid is substituted for citric acid in the early stage of development, the details may be brought out and a soft picture produced after a shorter exposure, but the amount of advantage gained in this way has not yet been accurately determined. One part of pure formic acid of the strength sold retail at fourpence per ounce, may be mixed with from one to six parts of a twenty-grain solution of nitrate of silver. The mixture may be made in small quantity immediately before being used, but it has been found to work well after being kept in a bottle for some weeks in the dark room, although a slight deposit which adhered to the sides of the bottle was formed in a few hours. Formic acid keeps the imago and the developer clear very effectively, and, if used in larger proportion than necessary, it does not prevent the fainter impressions of light from coming out to the same extent as would citric acid under the same circumstances. Nitrate of silver solution, acidified with formic acid, works well without filtering, even after being long kept; it does not, however, produce intensity so readily as the citric acid and nitrate of silver solution; it will, therefore, be advisable to add a little of the latter to the developer to finish with.

The value of ammonia in development appears to be fully established, and is described here with much minuteness. It is another illustration of the singular coincidences that frequently happen, that the use of ammonia in development should have occurred to two or three persons simultaneously and independently. The announcement that diluted ammonia would develop a tannin plate was first published, we believe, in our columns, in a letter from Mr. Leahy, of Dublin. Major Russell, it appears, had, at the same time

(last autumn), been engaged in experiments which led him to the same conclusion; in both cases the American suggestion of fuming having led to the further discovery. Major Russell says:—

It has recently been discovered that ammonia may be used as a developing agent with dry plates. The writer, on reading an account of fuming tannin plates with ammonia in America, was led to investigate the subject. As it seemed probable that the developing effect was produced by some action on the tannin, the first thing done was to try the effect of ammonia on pyrogallie acid, which, being a much more unstable substance, was expected to act more strongly. This expectation was fully borne out by experiment; the mixture of a very small proportion of ammonia with pyrogallie solution produced no immediately visible effect, but after a short time the liquid began to discolour in the same way as if nitrate of silver and an acid had been mixed with it. If, immediately on being mixed, the liquid was poured on an exposed plate, a powerful developing action was set up, and when the necessary conditions had been found, it worked with great certainty. Further experiments showed that tannin, when mixed with ammonia, would act as a developer, but with less energy than pyrogallie, and that it therefore required a longer exposure. Gallic acid used in the same way appears to be intermediate in its effect between tannin and pyrogallie acid.

Fuming with ammonia has been tried. The effect with the tannin is greater than when the ammonia is applied in a liquid state, but still inferior to that with pyrogallie, for when the latter is added to the liquid used for moistening after the fuming, and poured on the plate, much more detail is brought out, and the result will then be much the same as if the ammonia had first been applied in liquid. The fuming does not seem to be so good a plan as the wet method, as it is more troublesome and uncertain, for in this way it is not easy to obtain exactly the right amount of the action of ammonia, and any great excess of this is injurious; if, on the other hand, the action is insufficient, very little effect will be produced unless ammonia is afterwards applied with the pyrogallie: the tendency to loosen the film appears to be about the same with both methods.

Commercial carbonate of ammonia answers better as a developing agent than solution of ammonia, for when the best proportion of each is used, it brings out the impression after an equally short exposure, with greater intensity, and keeps the picture rather brighter. If carbonate of ammonia is used, it may be kept in solution of any convenient strength; if solution of ammonia is used, one drop of the strongest usually sold may be mixed with one ounce of distilled water: for use, about the best proportion appears to be one grain to one grain and a half of the carbonate, or three-quarters of a drachm to one drachm of the diluted solution of ammonia, and one grain of pyrogallie in from two drachms to one ounce of the mixed developer. The strength of the developer within these limits will make but little difference, except that the stronger it is the quicker will be its action; if too strong, the transparent parts of the negative may be just perceptibly veiled; the more diluted the developer, on the other hand, the brighter will be the picture.

The plates may be moistened with diluted alcohol, in the manner already described for the acid silver development, and when the distilled water will flow freely it is to be poured off, and mixed with the carbonate of ammonia in solution, and then poured on and off the plate a few times. If the alcohol and water has acquired much tannin from use, this mixture will make a very good developer, and will bring out all the details, if a sufficiently long exposure has been given; if not, pour off the liquid, add the pyrogallie, and mix well, and return to the plate; the image will immediately show more detail and darken considerably, the image brought out by the tannin being paler and redder than that produced by the pyrogallie.

The following method of commencing the development is, perhaps, on the whole, better, certainly easier, but involves the expenditure of more alcohol:—Dissolve six grains of carbonate of ammonia in two ounces and a half of distilled water and one ounce and a half of alcohol, sp. gr. about .830 (1); this liquid may be kept ready mixed in a bottle. Dilute five minims of the alcoholic solution of pyrogallie* to two drachms

with the same proportions of alcohol and water as in the carbonate of ammonia solution (2). Measure out as much of (1) as will cover the plate (two drachms will be amply sufficient, if of stereoscopic size), and one-fourth the quantity of (2). Pour (1) over the dry plate on a levelling stand; it will flow freely, but still more so if a larger proportion of alcohol is used. Pour on and off two or three times, and watch the effect; if the tannin has been applied in weak solution, and especially if it has been washed off again, there will not be much developing action, but if the exposure has been sufficient there will usually be enough to give an indication as to the kind of treatment likely to be required. Next pour off and mix with (2), pour on again immediately, at the far side of the plate, carrying the measure along from end to end, with the foot turned from the plate, to prevent the possibility of dirty liquid falling on the film, and tilt the plate quickly, so as to drive off all remaining moisture before the mixture into the measure; in this way the development will be started evenly all over the plate. If the solutions of carbonate of ammonia and pyrogallie do not contain about the same proportion of alcohol, the mixed liquid will not flow freely. Pour on and off quickly two or three times, then let the plate remain at rest, covered with the developer, and carefully observe the effect.

If the appearance of the image indicates that the exposure has not been too great, the alkaline developer may be left to act for some time, but if the image shows symptoms of over-exposure, pour off and wash the plate quickly; in any case when the development with ammonia has been carried far enough, before intensifying with silver, the plate should be washed for several minutes under a stream of water, and then placed on a levelling stand, and left covered with water for a short time. After this the development may be completed with pyrogallie and acid silver, the proportions of which should be regulated by the appearance of the image, just as if the development had been commenced with the acid silver developer; by this means, and by varying the duration of the action of the alkaline developer, any error in the exposure can be corrected within certain limits. If, from under exposure, the alkaline developer fail to bring out sufficient detail, there appears to be no remedy; changing the developer for a fresh one of the same kind seems to be quite useless.

The acid development will bring out nothing which failed to appear before, and, therefore, very strong pyrogallie solution will not be needed; but by using at first a small quantity of silver solution which does not contain a very large proportion of acid, all the details faintly brought out by the alkaline developer will be established. By washing off quickly, and then intensifying with weak pyrogallie and a large proportion of acid silver, over-exposure can readily be corrected. The effect of varying the proportions of the pyrogallie and ammonia, to suit the development to the exposure, has been tried, but this plan does not seem to answer as well as the one just given. For landscapes, four grains of citric acid to each grain of nitrate will usually be required to prevent blurring, when the collodion contains iodide, as the tendency to this fault will be fully as great as if the development had been commenced with silver; for the same reason the plates should, in this case, have been prepared with as weak a solution of tannin as will work well.

If the exposure has been sufficient, the image comes out very quickly on the application of the pyrogallie and ammonia, and is at first of a more or less red tone, and has much the same appearance as if silver and acid had been used; the colour of the image soon becomes darker, the liquid darkening at the same time. If the plate has been rather under-exposed, the alkaline developer may be left on for many hours without producing any deposit or fogging, or the mottled markings so often brought out under similar circumstances by a developer containing silver; in this way, at last, a considerable amount of intensity may be obtained, by a reduction of silver so complete that the image will bear fixing with weak cyanide without being very perceptibly weakened. The intensity thus produced is of no practical value with bromo-iodized collodion, as it may be obtained in a few minutes to any desired extent by the use of the acid silver developer, and a better result will be thus obtained. With bromized collodion, if the exposure has been suitable, the alkaline developer will often produce sufficient intensity* without causing any bad effect if left to act for several hours, during which the plates require no attention.

* Pyrogallie acid	96 grains
Absolute alcohol	1 ounce
Ether	3 drops.

* In printing from negatives of low intensity, it is necessary to use highly

The interesting subject of alkaline development is entered into with considerably more detail, and we strongly recommend our readers to study the chapter in Major Russell's book. Hot development has not been successful in Major Russell's hands, and he does not recommend it, as although he finds that an image may be forced out by its aid after short exposure, he finds it to be superficial and generally worthless.

Fixing.—The author prefers hyposulphite of soda to cyanide of potassium, as a rule, on account of the tendency of the latter to loosen the film.

Both in the course of the work and in a final chapter the various suggestions which have been made for modifying the tanning process are considered. Applying the tannin solution without removing the nitrate of silver, is found to give stains. Washing after applying the tannin solution is found to increase sensitiveness. Gum used with tannin has a tendency to cause blisters and fogging, but increases sensitiveness. Mr. Keene's method of applying gum and tannin without washing away the free nitrate, may be used, provided sufficient formic acid be added to the preservative, but no accession of sensitiveness is gained by the presence of the free nitrate. Honey and tannin are found to work well, but the advantage of the honey is only found in hot dry weather. The addition of dextrine causes loss of sensitiveness and loosening of the film. The addition of glycerine gives no advantage in winter, but may be useful in hot dry weather. Indeed, whilst tannin may be used in conjunction with a great many other preservatives, almost everything which has been tried has had, in Major Russell's hands, the effect of blurring the edges of the lights, or of diminishing sensitiveness, or of loosening the film, or of being altogether neutral in producing results.

We strongly commend our readers to obtain this little volume, which is full of suggestion, the result of much experience, and the most careful observation of, and reflection upon, the varied phenomena, presented by dry plate photography.

SENSITIVE PLATES AND THE CUSTOM HOUSE.

THE question is frequently raised by intending tourists on the continent as to what facilities exist for sensitive plates passing the various continental custom houses without being exposed to light. We have been asked recently whether any special facilities would be afforded for sending English contributions to compete for the Marseilles rapid dry plate prize. Regarding the latter we have written to M. Vidal, the Secretary, and have not yet received any answer*; but as the general question is an interesting one, and has not, as yet been placed upon any definitely understood footing, we have pleasure in publishing a letter we have just received from Mr. Cole, detailing his experiences in this direction.

The box which he kindly forwarded for our inspection, affords every facility for examination without any risk to the plates. The four pieces of glass, each about two inches square, are of a very deep green, and placed opposite each other, so that the light passes right through. We append copies of the inscriptions, one in French, and the other in Italian, to be placed on each box, for the benefit of those who may be desirous of following out the method Mr. Cole has found successful:—

salting paper and some method of toning which reduces considerably. In all cases the darkest parts must reach or nearly approach the bronzing stage, or the positive will be wanting in vigour; with a faint negative, by the time that the shadows are deep enough, the most opaque parts will be printed through. A toning mixture which has sufficient bleaching power will clear the lights of the picture without reducing the shadows too much, and so produce a brilliant positive from a somewhat weak negative. This is perhaps the best way of working, for it is much easier to obtain a good negative of low than of high intensity, the gradation of tone being often injured when intensifying is carried far. No time is lost in this way, as faint negatives print very quickly.

* We have received a communication from M. Vidal, just at the moment we go to press. It shall appear in our next.—ED.

Cette boîte contient des plaques photographiques très altérables à la lumière ordinaire; si elle est ouverte au grand air, les plaques seront complètement perdues.

Messieurs les officiers de la Douane sont, des-lors priés d'avoir la bonté, de regarder dans l'intérieur, au travers des verres de couleur, qui y ont été adaptés exprès pour faciliter la vérification; et ils pourront par là aisément se convaincre, que la boîte ne contient, ni cigares ni aucun autre objet de contrebande.

Questa cassetta contiene vetri preparati per la fotografia facilissimi a quastarsi al contatto dell'aria.

Se la cassetta viene aperta essi sono intieramente rovinati.

Si prega l'officiate della Dogana ad avere la bontà di osseroare a traverso dei vetri colorati, e vedrà che la cassetta non contiene nè sigari, nè altri oggetti di contrebande.

DEAR SIR,—As to sensitive plates reaching Marseilles unexposed at the Custom Houses, and as the time for tourists is come—yet more because you say you will make inquiry—I venture, unasked, to send you a plate-box which has passed the ordeal, with several others, through France, Switzerland, and Lombardy. All were sent from Turin by Diligence home before me, with key attached, and upon development they certainly had not suffered from Custom House officers' inspection. In both the top and bottom of the box are let in two pieces of yellow glass, about 2½ in. by 1½ in., and 3 in. apart, in rebates, and secured by small deal slips (any carpenter can do this). Outside of the yellow is a piece of green, rather loosely fixed by ordinary stout needle-points. This I put to take any blow, and get crushed instead of the yellow. Pasted on the side of the box is a request in French and also Italian, to Messieurs les officiers, to have the goodness to look through the yellow glass, and see that the box contained no cigars nor other contraband; and look through, they always did, upon reading the civil request and the reason for making it. An eminent Photographic house having seen one of my foreign boxes, has, I believe, copied these petitions into their year book (possibly with better French), but I think, unfortunately, without telling that the arrangement has actually stood the test in anybody's hands, which is the very thing that your subscribers would, perhaps, like to know. You yourself may find better means of security. I only think you will allow me to send my contribution.

You will see that I have used boxes for six only. An official will not lift to a gas light a dozen box of 12 by 10's. Besides, these require no handles, and therefore pack pleasantly, and, as breakage occurs, it is better to lose a few than so many, from the ramblings of a fragment of glass.

If I may write on, I would say that long railway and diligence shaking so often causes the glass edges to part with small bits or dust to travel over the film, and that as tight packing inside the cover will be sure to crack a plate on the first throw off on to a platform, I should, another time, ask Messrs. Bland to make the boxes with covers at the bottom (it sounds Irish) as well as at the top, so that all four corners of the plates may be got at and wedged with cardboard, to keep them free from the grooves. And commend me to a box with the extra 1s. 6d. expense of two locks and one key, instead of those hooks which always will get loose when one wants the ends to be the tightest.

To repeat, do not omit the green glass protection; it is agreeable to the foreign eye to look through green spectacles. I will, at all risks, add that I kept each box in a loose yellow calico case, as extra protection from light, and I found that the opening it gave time for a polite caution and a polite acquiescence. It was in 1861; every year would afford increased attention to photographic plates probably.—Yours truly,

JOHN J. COLE.

24, Essex Street, Strand, 24th Aug. 1863.

PHOTOGRAPHY IN AUSTRALIA.

BY PAUL RICOCHET.

THE "old folks at home" know, for the most part, very little about the colonies. Those among them who are considered well read on the subject, have at best only a hazy idea of the actual state of matters at the antipodes. A dim vision floats across their mental sight, of a wilderness of sheep-stations, where hardy bushmen (subsisting chiefly on kangaroos) dwell armed to the teeth against the frequent attacks of hostile natives.

Also, it is difficult to make people understand that Melbourne is *not* in the same island as Hobarton, and that the towns on the continent are *not* within an hour's walk of each other.

"Ah! Mr. Ricochet," said a lady to me once, "I hear you intend making a voyage to Melbourne. I wish, during your stay there, you would call on my son, he would be so pleased to see one of my old friends."

"Delighted to do so my dear madam. What is his address?"

"7, George Street, Rockhampton!"

Now, Rockhampton is just one thousand miles from Melbourne, rather too far for a morning call!

As may be gathered from the foregoing conversation, I had at that time an idea of taking a trip to the colonies, and this idea was carried into execution some two years ago.

The following paragraphs contain a few extracts from notes taken during the trip, and may probably interest the readers of the PHOTOGRAPHIC NEWS.

"Tannin" not being then in vogue, I provided myself with a tent, wherein was found every requisite for working the wet process in the field, and having packed up therewith a 9 × 7 instrument, with single and double combinations of lenses, and all necessary chemicals, started by one of the Blackwall Liners, in which a pleasant voyage passed without accident.

On Tuesday, November 17, 1861, I had my first view of Australia.

A long low stretch of rugged coast, extending on either bow as far as the eye could reach, the monotonous grey rocks broken into an opening ahead, where two cliffs formed the gate posts of a line of surf, inside which could be seen for many miles, a vast expanse of calm water,—Hobson's Bay. The same evening, we arrived at Sandridge Pier.

To one coming from London, Melbourne presents few remarkable features. It is in fact, as many declare, a miniature London. The same 'buses, cabs, and vans throng the streets, morning, noon, and night, and the diurnal clatter and roll of wheels is well nigh as deafening as in any section of the modern Babylon.

Nor is the resemblance less striking in the matter of photography. Every second house in the street is either a photographic shop, studio, or warehouse; and yet, with all this competition, the profits made by some of the leading houses are enormous. One can get one's "carte" as well taken here as in London, at any price from 3d. to 10s.

I did not notice much *landscape* photography going on, even amongst amateurs. The truth is, Melbourne and its suburbs are hardly picturesque enough to tempt even the most enthusiastic devotee of his art. There is scarcely a decent view anywhere—the country is flat, tame, and uninteresting.

After a few weeks in Melbourne, I determined to take a trip over to Tasmania, and spend some time amongst the varied mountainous scenery with which the island abounds. For this purpose, starting one afternoon by steamer, I arrived in Hobarton just forty-eight hours after leaving the Melbourne wharf.

It was early in a fresh spring morning as we passed at half speed up Storm Bay, going close to the lighthouse at the entrance of the river Derwent, which lighthouse, by the way, bears the euphonious name of the "Iron Pot," whether in delicate allusion to its architecture, or not, I could not learn.

Rounding a point in the river, we came in sight of Hobarton. Mount Wellington, rising steeply some 4500 feet above the water, forms a grand background to the town, whose white houses, mingled with tufts of lofty trees, are sprinkled over several small rises along a bend in the Derwent; points, thickly clothed with dusky foliage, jut out from either bank, and the whole landscape, surrounded and shut in by ranges of hills, and reflected deeply in the broad, calm bosom of the river (which is here three miles wide) formed a picture I had rarely seen equalled.

My first care, after securing lodgings and a man to look after my concerns, was to ransack my photographic packages. Everything was in perfect order; the collodion (principally Bland and Long's), had stood the voyage famously. By the way, let me here recommend all tourists by sea voyage to carry their instruments and chemicals in air-tight tin boxes soldered carefully up. If this precaution be attended to, the risk of danger is small.

Although I was well satisfied at having brought with me all necessary chemicals; there was in fact no actual necessity for so doing, as chemicals by all well-known makers can be bought in Melbourne. In Hobarton too, one can now, I believe, get any requisite; but at the time of my visit there was no first-rate photographic warehouse established there.

Every one advised me to ascend Mount Wellington; and as my own inclination coincided with the advice, and as my servant (an Irishman, by name O'Corcoran), professed himself thoroughly well acquainted with the route, I started one fine morning on this my first photographic essay in Tasmania.

Mr. O'Corcoran and myself trudged merrily along, he with the tent and chemicals, and I with the instrument. After a couple of hours walking along a steep stony track, we reached a terrace called the "Springs," which is considered half way to the summit. Here a rivulet of cool, clear water issues from a rocky cavern, and falls away down the mountain side. This cavern, with overhanging shrubs and brushwood, formed a charming subject for the camera. I was disappointed in not getting the view from this spot of the town and surrounding country, which is very fine. My failure was, I believe, owing to the too strong contrast between the foreground, which was dark and sombre, and the distance, which was very bright.

In this trip I gained several experiences. One was that the wet process, with a tent, is nearly useless in Australian photography. With the thermometer at 98° in the shade, the interior of a tent is like the *sudatorium* in a Roman bath; and added to this, there are frequent hot winds, which cover your plates with fine dust, and often blow the tent over.

What strikes an English photographer very forcibly in Tasmania, is the translucency of the atmosphere. On this account distances, even when remote, may be photographed with remarkable distinctness and perfect definition. I never saw a country so free from fogs of all kinds; indeed, the only fog I ever saw there was once on a swamp, and in that case it covered so small an extent of ground, that when one walked for fifty or a hundred yards up any one of the surrounding hills, one could see the fog lying like a tuft of cotton wool on the little swamp below.

After spending a month pleasantly in Hobarton, I packed up my traps, and began my travels through the island. Warned by previous mishaps, I left my cumbersome tent at home, taking instead a store of collodio-albumenized plates, warranted to keep "any length of time."

I was rather successful with this kind of plate. I found their keeping qualities equal to my wants: for instance, I managed to keep them, when sensitized, for upwards of five weeks, which, in a hot climate, is a term not to be despised. My formulae were as follows:—For the iodized albumen, dissolve 7½ drachms loaf sugar, 36 grains iodide of potassium, 36 grains iodide of ammonium, and a scale of pure iodine, about the size of a barleycorn in 9 ounces of distilled water. Add to this solution the white of 9 eggs, and beat the whole into a firm froth. I preferred the eggs not quite fresh, believing that when in this condition, the film produced was less likely to blister. I used any old collodion, a forty-grain nitrate bath, and great care in cleaning the plates. Also, copious washings* at every stage of the process.

(To be continued.)

* I found using half a dozen buckets filled with water, each in succession as dipping baths, an excellent plan.

PHOTOLITHOGRAPHY.

II.

BY JOSEPH LEWIS.

VARIOUS METHODS OF OBTAINING AN IMAGE ON STONE.

THE desideratum in photolithography is to obtain a permanent impression on the stone or plate from which to print the copies; in fact, to assimilate the process as nearly as possible to that of transferring in the usual course of the lithographic art.

By the process of photo-printing from stone with direct application of the sensitive film to the stone's surface, we fail to get perfect results, owing to its very absorptive nature, for having once imbibed even a soluble substance, it is difficult to extract or dislodge it. For this reason I failed, in 1842, to produce perfect results by the use of bichromate and gum on stone, as also the bitumens. I then had recourse to the following expedient.

I coated the surface of a card with hard plate ink, this I brushed over with very finely divided pure silver powder or dust, and then passed the card through press on a polished steel plate. I produced the picture by the ordinary daguerreotype process, as if it were a silver plate. The picture thus obtained only remains to be etched by the galvanic influence, when the shadows, consisting of pure silver, are quickly etched away, exposing the transfer ink in deep contrast with the mercurial deposit, comprising the lights of the image. This, when washed in a solution of cyanide of potassium, and in water, and dried, is laid, face down, upon a clean, heated lithographic stone (brass, zinc, or iron plate answering also for the purpose), and passed through the press, when, as will be readily understood, the ink is pressed into close contact with the stone, and is absorbed by it, but the deposit of undissolved silver and mercury on the lights intervenes to prevent the ink under those portions from contact with the stone. We have thus a reliable transfer wherein every mark or indication is permanently fixed in the stone and capable of great endurance in course of printing, for this plain reason—the surface of the stone is perfectly clean and the ink substantially greasy.

Closely connected with the above manner of manipulation, and also with the process described in last week's number of the NEWS, is the following process, which possesses peculiar advantages, being more sensitive than the latter, and more simple in its application.

I form a jelly, consisting of four ounces of water, one ounce of gelatine, one-eighth of an ounce of glycerine, and bichromate to saturation at a temperature of 80 degrees. These are put into a glue-pot, and heat applied to dissolve—carefully filtered and spread on glass plates—then allowed to stiffen until the surface will not adhere to the dry finger, or stick to the negative plate when pressed against it. If the upper surface be not smooth, I reverse the film upon another plate or waterproofed cardboard, upon this I place the negative and expose for a few minutes according to light, and then withdraw to the dark. The exposed surface is to be laid down on a clean lithographic stone, and a very gentle pressure applied simultaneously on every part to ensure success. Some dexterity is required in laying down and quickly taking up the gelatine sheet, circumstances regulating the degree of pressure and the time it should remain in contact with the stone. This being accomplished, the stone is smeared with re-transfer or printing ink, and washed off with turpentine and gum-water; then inked up in the usual manner. A positive transfer will be the result, ready for printing. The same exposed surface may be placed on several stones, and yields a number of good transfers by a single exposure.

On comparing this process with that described in last week's issue, it will be seen that there is a connecting link, being opposites in every particular, except that they unite in giving a resultant positive image as a printing

surface. By the former, the actinic influence "stops out" the lights on the picture; in the present process the lights are procured in proportion to the intensity of the exposure. By each the exact sum of actinic result is preserved and deposited on the stone, whereby we obtain the natural amount of gradation and detail.

I repudiate as steps in the wrong direction, the various futile expedients recommended to produce a "grain" on the stone or plate, to obtain by artificial means that which nature itself can so effectually supply. There is no grain or roughness needed on the daguerreotype plate or the collodion film, yet there is absolutely perfect gradation. The only result of any attempt in that direction has been to destroy minute detail, and break up or destroy the intensity of the shadows, as may be seen by an inspection of the phototypic proofs.

PHOTOGRAPHY AS AN ACCOMPLISHMENT.

BY REV. S. MILLER.*

WE employ professors, and pay them well—some more than they deserve, others little enough—to give lessons to our daughters in music, drawing, and painting. These are desirable accomplishments for young ladies, provided something more than mere dabbling in them is attained, which is seldom enough the case. Hence, after leaving school, their productions seldom see the light of day, and there is no one to admire them. Just compare some of their best productions with the fine pictures, so life-like and true to nature, which any lady is able to produce by means of the camera, in half the time and at half the expense lavished on her other accomplishments, and you will be surprised at the vast difference.

There is no reason why photography should not be introduced and taught as a female accomplishment. There would be something real in such an accomplishment, producing infinitely more pleasure and admiration than any of the imperfect productions by means of brush and pencil.

A piano and a camera. A family parlour and a family gallery. A library and a laboratory. Your dear friends from abroad come to see you, and you part with them perhaps for the last time. They are gone, but before they got away you caught and fixed their lovely image in your camera, and you keep that instead of their presence. You make a rare and beautiful collection of the portraits of living and departed friends—a family gallery of pictures; and it is *all your own production!* What pleasure in the thought. And you need not blush to let them be seen by your visitors and friends, nor indeed by any of the best artists. They are the productions of real art and the most beautiful art which you can practice.

I am teaching my daughters and sons the art, and I mean that my family shall possess the best instruments and materials to practice it. It affords them already a great deal of pleasure, and makes home sweeter and more attractive than anything else that I have yet introduced in the way of rational amusement. Louisa, the oldest, is very successful in taking the finest portraits on glass. Master Charley is a real little artist, and takes first-class card pictures, equal to some of the best produced in large establishments. He reads and loves *Humphrey's Journal*, and is ever on the alert for some new experiment. I herewith enclose you some of his proofs, one the portrait of his sister Phene. She, too, is beginning to show her hand, and has succeeded in producing some beautiful ambrotypes. And Clara and George are impatient to try their hand. It not only affords them much pleasure, but may prove a benefit to some of them hereafter.

In this connection I must relate quite an unexpected and very important "result." The oldest daughter, Louisa, who has somewhat of an enterprising spirit, took it into her head to try the experiment to operate for the public. A

* From *Humphrey's Journal*.

vacancy occurred in a neighbouring town, in the heart of our extensive coal region, and I was requested to send them an operator, as pictures were much in demand. She was determined to go, more for the novelty and excitement of the thing than any profit she expected to reap. To gratify her anxious desire to try the experiment I had to part with my instruments for a time, hoping she would soon get tired.

She made her temporary home at the principal hotel in the place, and I introduced her as a minister's daughter to the landlady and a clergyman boarder, the Episcopal minister of the place, who promised to take good care of her.

She succeeded remarkably well for a time, myself having seen that her bath and collodion were in good working order, and she took the portraits of her customers, both young and old, to their mutual satisfaction. She was rapidly gaining the reputation of being a good artist, and customers increased from day to day. But in taking the portraits of the clergyman and a certain member of a corps of engineers, who were locating a new railroad in the neighbourhood, she got fairly "stuck." They both fell desperately in love with her, and the only way to get out of the "difficulty" was to refuse the one and accept the other. The "result" of her experiment as a practical operator was a wedding, the ceremony of which was duly performed by the father of the bride in presence of his congregation. The result proved highly satisfactory all round, except to the disappointed party.

Her husband, immediately after the wedding, put a "stop" to his wife's operation as a photographer, insisting that "she didn't gain anything by it." "Didn't gain anything by it," she replied, "didn't I gain a husband by it?" He had to admit the fact, but allowed that quite sufficient, to which she finally agreed; so I got back my instruments to make other experiments, the results of which are not quite so romantic, but some of them nevertheless worth recording.

ALBUMENIZED GLASS PROCESS.

BY CHARLES WALDACK.*

I HAD occasion a short time ago to see some stereoscopic slides made, by the albumen process, by Mr. Ferrier, in Paris, and I was so much struck by their beauty and fineness, that I have ever since been in a fit of enthusiasm about them. That the process by which they are made presents incontestable advantages over all others, for such kinds of work, cannot be denied by any one acquainted with its results. The objection is urged against it, that it is of great difficulty in execution—that it is difficult to get an even film of albumen, to avoid dust, &c.; and these fancied difficulties have led to its being practised only by a very small number of photographers. Now, I have had occasion to hear the story of successful practitioners of the process, and they assert that these difficulties have been much exaggerated, and that with a little practice it is just as easily worked as the collodion process.

This has encouraged me to give your readers a description of the process practised by Mr. Ferrier, as communicated to me by a friend.

Take 20 oz. of the whites of fresh eggs, out of which the germ has been removed, and add to it 100 grains of iodide of potassium and 5 grains of iodine previously dissolved in a little water; beat in the ordinary way. If you don't know how, consult any work on photography. Our formula stands thus:—

Albumen	20 fluid ounces
Iodide of potassium	100 grains
Dry iodine	5 grains.

Clean out your room the day before, not only the floor

* From *Humphrey's Journal*.

but also the walls, sables, &c., and in the morning sprinkle with water. Now, have a large alcohol lamp or several small ones, or—what is better yet—a gas lamp such as is used for cooking by gas (Bunsen's lamp); put a support over it, and lay on top a thick sheet of iron plate. The glass, being well cleaned, is coated with the well deposited albumen. This is done in the following way:—Condense the moisture of the breath upon it, and pour on albumen in the same way as collodion, pouring the excess into another bottle. Breathe again on the parts which are not yet recovered, and pour a fresh portion of albumen on those parts. Obtaining in this way a film all over the glass, the excess is drained off, and the plate is hung by its corners on four silken threads of equal length, having a hook at one of their ends; the other end of the threads being held in the hand, the plate is kept over the hot sheet of iron and a rotatory motion is given to it. The albumen is spread evenly all over the glass by the centrifugal force, and the drying is accelerated both by the heat and by the motion. Very few minutes are necessary to dry a plate in this way. When dry it is put into a grooved box and another one coated. The sensitizing is done in the following solution:—

Distilled water	14 ounces
Nitrate of silver	1 "
Glacial acetic acid	2 "
Iodide of potassium	2 grains.

The bath is prepared the same as for collodion. I suppose 6 oz. of acetic acid, No. 8, may be substituted for 2 oz. glacial, using then only 10 instead of 14 oz. of water. The sensitizing is done in from 15 seconds to 1 minute. The plate is then washed under a tap and put to soak in clean water. Any other way of washing used for dry collodion will answer. After being well deprived of its nitrate of silver, the plate is set to dry and placed in a grooved box in the dark room.

I have not been informed how long the plates thus prepared remain sensitive. However, I know they can be used several days after, and suppose they will keep as long as any dry collodion plate if well freed from the nitrate of silver.

The exposure is about the same as in the tannin process, when old collodion is used perhaps somewhat longer. The development is done as soon after the exposure as possible. The plate, if exposed long enough, shows traces of an image before development. This operation is carried on in the following way:—Make a solution of gallic acid, 1 grain to the ounce; pour it into a vertical glass bath, and set the bath in warm sand at 120° Fab; the plate is then put into it, and left there for one or two hours. This is done to soften the albumen film. After that it is put into another vertical bath containing a cold solution of gallic acid to which 5 or 6 drops of fresh silver solution have been added. In this bath the plate develops rapidly, and when the image has almost entirely appeared take it out for a moment, and add to the gallic acid 3 or 4 drachms more of silver solution. The plate being dipped again, the image acquires its greatest vigour and is washed and fixed with hyposulphite of soda.

The operator should well convince himself of the fact that the colour of an albumen negative obstructs the actinic rays more than that of a collodion negative, and that, in consequence, the deposit need not be so dense.

Transparent slides are made by exposing an albumen plate under a negative for a few seconds to the light of the sun. The pleasing colour of Mr. Ferrier's slides is given by dipping the finished positive into a weak solution of bichloride of mercury, washing it, and then dipping it into a solution of chloride of gold, 1 grain to the oz.

If I have thus returned to this old and much abused process, it is, Mr. Editor, because I think it may prove profitable to your readers. If any of them have an opportunity of seeing some of Mr. Ferrier's slides, I am certain that they will be of the same opinion as I am about them—that nothing on either wet or dry collodion can compare with them.

THE NEW GOLD TONING BATH.

BY REV. S. MILLER.*

I HAVE long since felt that the gold toning bath neutralized by means of carbonate of soda, or in which any of the sodas are added for any purpose whatever, could not give permanent satisfaction. The loss of gold for photographic purposes by precipitation, and the inconvenience in manipulations, especially the former, was to me at least a very serious objection, and I felt satisfied in my own mind that there must exist a possibility to overcome this expensive waste by neutralizing the gold by means of a substance that would not cause its precipitation. In this, it seems, I have not been disappointed. Others have been exercised on the same subject, and have laboured successfully to overcome the evil. The remedy is found. I have tried the experiment with perfect success, and I cannot express how thankful I feel for the information I have derived from the pages of the Journal on this important subject. It pays me double the price in gold for the last three volumes. In my humble opinion, the time is come when the use of soda in the toning bath is entirely and for ever done away with, provided amateurs and operators will furnish themselves with the proper sources of information, such as *Humphrey's Journal* affords.

I will state my experience in this new process, and the peculiar mode of operation which I have adopted as the most convenient I could think of.

1.—I commenced by making a saturated solution of lime, half an ounce to 16 ounces of water, which contains about 15 grains to the ounce of solution. The bottle containing it is labelled accordingly.

2.—In another bottle I made the following solution: I dissolved 30 grains of commercial chloride of gold, pretty strongly acid, in 30 ounces of water, and added 30 grains of finely pulverized carbonate of lime (common chalk). This was well shaken and left standing for half an hour. To this was added 2 ounces of the above chloride of lime solution, containing about 30 grains. The whole was then filtered. This solution has a slightly alkaline reaction. None of the gold is precipitated, nor has the calcium materially changed its golden colour. This, however, is not the toning bath. The bottle containing it is labelled "gold and lime solution," and the foregoing formula added.

3.—Fifteen ounces of the above gold and lime solution are poured into a half-gallon bottle, and 30 ounces of water added. This is the standard toning bath, containing 15 grains of chloride of gold, 15 grains of carbonate of lime, 15 grains of chloride of lime, and 45 ounces of water. Perhaps a larger quantity of water would be better, as the bath is at this standard very vigorous. It does not require filtering. By the addition of water the gold solution has become almost entirely colourless, clear, and transparent, without the least deposit or precipitation. It is in appearance the next thing to a nitrate of silver bath, and I propose to treat it much in the same way.

4.—There are still 15 ounces of the gold and lime solution left, which is set aside ready for future use as occasion may require. When the bath becomes weak by use, one or two ounces of this solution is added to keep up its uniform standard.

The prints are thoroughly washed before putting them in the bath. They tone quickly, more so than when the bath is neutralized with soda. The toning does not materially bleach the prints, but the subsequent fixing does; for which reason the proofs have to be overprinted as usual. After fixing in fresh hyposulphite of soda, washing, and drying, the tones are a "rich deep black, quite free from meanness, blueness, or slateness in the shadows," &c. If not overtoned, they are unsurpassed by any results that I have yet produced by any other toning process.

What effect age will have on the foregoing concentrated "gold and lime solution," as a very ready and convenient means of keeping up the standard strength of the bath, I have not had time to test. But if time does not produce a change in the bath, the presumption is that it will not affect the gold and lime solution, probably even less than the diluted bath. If such be the case, and if no other objection will arise against the substitution of lime for soda, then indeed have we obtained the most convenient, the most effective, and the most economical process of toning with gold that can well be conceived.

* From *Humphrey's Journal*.

In a subsequent article the same writer says:—

As others intend to give the new gold toning bath a fair trial, and have questioned me in regard to my process of preparing it and its results, by private correspondence, I would state, for their information, that the bath I have prepared and kept up to its standard strength, according to the formulas given in my article of the 1st of March, has now been in daily use in my son's operating room for the last six or seven weeks with uniform good results. I find no occasion to make any change, except to renew the chloride solution, in consequence of not having kept it in a well stoppered bottle, by which neglect much of its chlorine has escaped, and chloride of calcium was formed. I would recommend that all the solutions, even the bath when not in use, as well as the dry chloride of lime, be kept in well stoppered bottles, to retain as much as possible their peculiar smell, which indicates the presence of the chlorine.

In this connection I would also correct a slip of the pen, which, though it does not affect the formula itself, has, nevertheless, made a wrong impression on the minds of some. In describing solution No. 1, the word "saturated" should not have occurred. The article I use is not the chloride of calcium. This compound, although entirely soluble in water, is a different and very inferior article. I use the chlorinated lime, the fumigating and bleaching agent of commerce, usually called chloride of lime. The article sold by druggists answers the purpose very well, but a more perfect and purer article could be produced, almost entirely soluble in water, which would answer photographic purposes still better, as it would contain more of the chlorine and retain it longer. It is true that chloride of calcium is present in the bath; but this, according to Omneganck (*vide* number for February of this journal), is formed by the free acid of the chloride of gold and a small portion of its chlorine combining with the carbonate of lime, the gold retaining the greater portion of its chlorine, whereby its precipitation is prevented.

Chloride of calcium is likewise formed when the chlorine of the lime escapes. The rationale why chloride of lime is added in addition to the carbonate of lime which of itself in sufficient quantity is able to produce the required alkalinity, is not given, but we are assured that it works well, and such I have found to be the case. It seems that the chlorine thus super-added to the chloride of gold, has something to do with the vigour of the bath and the brilliancy of the results produced. Hence the necessity of preventing the escape of the chlorine by useless exposure.

Great care has to be taken in the use of this process, that none of the fixing solution gets into the bath, or the whole is in danger of being ruined, as the hyposulphite of soda liberates the gold of its chlorine and precipitates it to the bottom. It is not only necessary to have the hands clean and free from soda before dipping them in the bath, but likewise in washing the prints before toning, and not to use a vessel for this purpose, in which prints after fixing had been soaked, without thoroughly cleaning it. We are apt unconsciously to carry the soda adhering to the hands or vessel into the water where prints are washed, where it will affect and impair the prints, and thence, adhering to the prints and hands, carry it to the toning bath, where it will, at first imperceptibly, but gradually and surely, do its destructive work.

I mention this fact, not only to save the bath, but to remind the operator that, if at any time his gold begins to precipitate, he can rest assured that the cause is to be ascribed to the old arch-enemy of all toning baths. He cannot be too closely guarded against, and should ever be kept at a respectable distance from the bath, until we can get entirely rid of him even as a fixing agent, and vote him out of every operating room in the land.

If by any accident soda should get into the portion of the bath in the toning dish, and evidence of precipitation appear, do not pour it back into the stock bottle if you value the rest of your bath.

If, in washing the prints, they become yellow and dirty, it is an evidence that they have been affected by soda either in washing or handling. Do not immerse the nasty things in your precious toning bath.

To keep the bath nice and clean, free from dirt and the effects of imperfect washing of the prints, filter the contents of the dish after toning back through a funnel, and your bath will remain clear and transparent.

I will yet add that it is presumed that those who will give the new process a fair trial are aware of one of the principal secrets of good toning, and that is, not to be niggardly in the use of gold. This process does not warrant the use of gold less freely than any other; but it saves the useless waste of the precious metal for photographic purposes, and greatly facilitates the manipulation, as you are not under the necessity of preparing a new bath daily for every batch of prints to be toned, and then be compelled to see with a sorrowful face the remaining gold go down, down to the bottom with its sulphureous enemy.

The attempt of saying it in other processes, by using it nearly all up in toning, is at the expense of uniformity of results; and as to using it all up before precipitation begins, that is simply out of the question. In the new process none of the gold is precipitated, and its uniform strength is kept up, hence the results are uniformly good, saving, in addition to its other superior advantages, much waste in paper, silver, and time, which are otherwise lost, because a weakened bath refuses to perform what does not lie in its power. Being given over to the power of its deadly enemy from the beginning of its existence, and its short life of an hour already in the throes of dissolution—poor thing; how can it help it? Save your bath from his clutches, and you will be all right. Give the new bath a fair trial, and keep him at a distance, and it will live to speak for itself, when all other processes in which he has his fingers are dead, and gone with him to the place from which there is no returning for evermore.

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, 26th August, 1863.

M. DAVANNE has called the attention of our Photographic Society to the advantages offered by the employment of sulpho-cyanide of ammonium. The observations he communicated are the result of experiments performed by M. Lewitsky and himself. Both have for several months made almost exclusive use of this new salt. They have proved that if it is slower in action than hyposulphite, it does not attack the thinnest film of silver deposited, and that the proofs fixed by it are superior to those treated with cyanide. M. Lewitsky recommends the employment of a very strong solution, containing at least 50 per cent. of the salt. M. Davanne applied this mode of fixing to *clichés* upon albumenized collodion (Taupenot's process) specially, and in consequence had nothing to fear from the albumen curling up, as was frequently the case previously. Practice, therefore, confirms the hopes that early experiments raised, and as M. Davanne observed, the great reduction in price already made by manufacturers, secures an extended use for this product.

M. Davanne adds, that sulpho-cyanide of potassium possesses the same qualities as the salt of ammonium, without any of the inconveniences attendant upon the latter.

M. Colombi, an optician, has exhibited to the Society an enlarging apparatus without reflector, which, he assures us, yields positive proofs in three minutes.

M. Morvan has addressed to the Academy of Sciences a note, accompanied with specimens of a new photolithographic process, which he describes as follows:—"Upon a lithographic stone, previously coated, in a dark place, with a varnish composed of albumen and bichromate of ammonia, I place the right side of the subject to be reproduced, whether the picture be upon glass, linen, or paper. Papier Saxe is naturally to be preferred. But any other sufficiently transparent substance suffices for this operation. This done, I expose the stone to the action of light, from 30 seconds to 2 or 3 minutes only, if in the sunshine; and from 10 to 15 minutes, at the most, if in the shade. At the end of this brief time, I remove the subject and wash the stone, at first in soap water, and next in pure water, and I immediately

pass over it an inking roller. The design is already fixed, for the picture begins to reveal itself in black upon a white ground. Then I gum it, and leave it some minutes to dry, and the operation is concluded; we can then pass it through the press and print from it.

"It will be understood that the light fixes the varnish and renders it insoluble wherever it strikes upon it; but that, on the other hand, all those parts of the stone shaded by the lines of the original design, remain soluble, consequently attackable by soda and by acid, in addition to what the substance of the soap contains; the action here produced upon the stone belongs at the same time to engraving and to lithography.

"As to the advantages of the process, they may be summed up as follows: simplicity and rapidity of operation; exactitude of reproduction; no need of *negative clichés* upon glass or paper; the *positive* model comes *positive*; absolute preservation of the model; intact and immaculate; permanency; at least equal to that of engraving upon stone; and, lastly, the great economy of the process."

We have already mentioned the labours of M. Eugène Baroux, who, for several years past, has sought the means of perfecting the application of photography to engraving on wood. M. Baroux, an experienced engraver, is better qualified than most others to understand and overcome the difficulties which stood in the way of his predecessors. We have seen the results of the new experiments he has made, and we believe that the problem of photography on wood is definitely solved. The image is as complete as the best proofs upon paper, and a skilful engraver can engrave it as easily as a design drawn by hand, for everything is rigorously indicated except the cutting.

M. Moisson addressed to the Photographic Society a supplementary communication upon his process of vitrified photography. He says:—

"The locality of the exposition has made me see in my vitrified photographs a defect which previously I had taken for an excellence, that is, their transparency.

"When the glass plates have the sky for a background, they are good; but when they are exposed to trees for a background, their transparency is injurious to the subject and fatiguing to the eyes, which, as in Daguerreotype plates, are compelled to seek the picture.

"To avoid this defect, and to give to the pictures a vigour similar to paintings on glass, I submit them to a second baking, after having covered them with a flux (glass, to which a small quantity of calcined bones is added) on the same side as that on which the picture exists: this is very important, for the salt of silver of which the image is formed is developed with greater intensity under the action of the flux, and gives a semi-transparency to the picture, which no longer fatigues the eyes.

"It will be understood that the process I have described is applied only after having done everything indicated in my previous communication."

M. Blaizé presented to the Society a series of proofs, many of which were obtained by the tannin dry process; they were accompanied by the following note:—

"The method I adopt is that which I have found in the treatise by Major Russell. I have only suppressed many details, which appeared to me useless. I make use of my usual collodion and nitrate bath, and avoid special preparations; I suppress the gelatine, and I varnish the edges of the plate before developing. I found the success of plates much surer than with wet collodion; their only defect is in the length of exposure, which must be long to avoid too much *teasing* the negative under development; that, in fact, is the chief point in this method.

"Tannin plates appear to me good the end of a year, and I have developed old plates many months after they were exposed, which gave good results. This process is perfect for reproducing designs upon white grounds, on account of the vigour which may be easily obtained. I have, by this method, reproduced many designs by Gustave Doré, and I

obtained as much success, and, perhaps, more delicacy of detail than with moist collodion.

"Many amateurs have commenced with me the practice of this process, and all have found it excellent. For, in all our excursions, we have been able to take certain subjects that we could not by other methods."

M. Hulot made some remarks upon parchmentizing and splitting of paper, and he repeated in the presence of the Photographic Society an experiment, the results of which, known to some persons for several years past, have hitherto remained unpublished.

He takes a sheet of paper and immerses it in commercial sulphuric acid, diluted with about one-fourth its weight of water, and quite cold. The time of immersion is from twenty seconds to a minute or more, according to the nature and thickness of the paper. The sheet is next washed in abundance of water and partially dried between folds of bibulous paper, or in the air. By means of a penknife or the fingernails the paper is split open at one corner, first cutting into the margin an eighth of an inch with a pair of scissors. The separation being effected at the edge it may be continued with the greatest facility, whatever may be the dimensions of the sheet to be split.

M. Hulot remarked that other means exist of splitting paper which, although he would not submit a costly engraving to it, he employs to split in two paper printed on both sides.

This experiment is founded on a property of the material of which paper is made—cellulose—of being transformed, in presence of sulphuric acid, into dextrine or glucose. The commencement of the parchmentizing which results preserves the external portion of the paper from the action of the weak sulphuric acid, while the interior substance is submitted to its action and softened. Hence the facility of separating in two surfaces lightly parchmentized.

The president, M. Regnault, inquired if, by a peculiar method of drying, it was not possible to destroy the effects of contraction in the paper, and if it were not possible to split a sheet of paper of which the surface only has been parchmentized.

M. Hulot replied that he has split printed papers, and arranged the opposite sides on one page by gluing them upon a thin sheet of paper; dried, beaten, and inserted in a volume, by a binder, it kept in perfectly good condition. We can glue the paper to be split upon another sheet, or upon a glass plate, so as to expose only one side to the action of the acid; and it is by analogous means that we are enabled to separate several successive thicknesses of the same sheet of paper.

M. Nadar, the eminent photographer, appears to have solved the problem of aerial navigation, or, as he terms it, *Auto-locomotion-aerienne*. M. Nadar employs a screw propeller and inclined planes. He fully recognizes that his theory is not new, since, in 1768, fifteen years before the ascent of the first Montgolfier, Paucton, the engineer, predicted that the screw would be employed in aerial navigation. A society of French and English capitalists is in course of formation for the purpose of constructing a gigantic balloon, to carry eighty persons, in a car of two stories, and which will carry everything necessary for comfort and convenience, even to a printing press. The diameter of this balloon, the proportions of which have never been imagined even in the speculations of American newspapers, will be nearly three-fourths of the height of the towers of Notre Dame. The Lyons manufacturers have already supplied twelve thousand metres of white taffety for its construction, and it is expected that the monster balloon will be ready for the Baden races, next month. The first voyage will occupy eight days and nights, and most of the seats are already engaged.

It has been proposed to counteract the sulphurizing of positive proofs by treating them with chlorine.

The Photographic Exhibition in the Champs Elysées will continue open until the end of the present month, between the hours of 9:30 a.m., and 5:30 p.m.

A DIFFICULTY IN THE TANNIN PROCESS EXPLAINED.

SIR,—A short time ago you were so good as to give me some valuable hints on Major Russell's new process, and also to obtain from him more full details of the process, for which please accept my best thanks. I have since been experimenting with it, and, with the aid of the Major's new edition, have got some negatives which are very nearly perfect. I have still, however, one difficulty, which I shall presently describe, and which neither he, nor any work I have on the subject, mentions; it is this:—

On taking the plate out of the exciting bath, it is covered over with small projections, some not larger than a pin's point, others as large as the head. On close examination, these do not appear to be like a deposit, nor are they at all visible by transmitted light (until developed), but look as if there was a small bell of air or gas under the collodion film; these little projections entirely subside on drying the film; but, I suppose, from containing more tannin or other matters than the rest of the film, are less sensitive, and show, on developing, a clear, round spot, with a dark ring round it. Thinking it might arise from the collodion being too thick, I diluted it both with ether and equal parts ether and alcohol, but still the same spots. Then I thought it might arise from ether in the film forming vapour by the heat of the atmosphere, and allowed the film to get almost dry before immersing in the bath; still the same result, even apparently a little more. Then I thought perhaps the film should be immersed wet, and did so when the collodion ceased to drop. Then I tried whether a thicker coat of gelatine would help it, and made a 4-grain solution, having previously been working with 2½ grains, but still the same result; and now I do not know what to do, but have to-day made the bath alkaline, and put it in the sun, although it works well otherwise, and do not think it is impure, and, if so, cannot understand how any deposit could raise these little bubbles.

I may mention further that the projections are not so perceptible when the plate first leaves the bath as they are when in the distilled water, nor then so much as in the common water. This, I suppose, is because the fluid is more dense round them, and conceals them. I notice that an excited and washed plate, if taken into daylight, comes out in dark blue spots where these prominences are.

I have to go to the country in a few days, and have been anxious to get a few plates to expose, and should be exceedingly obliged if you could find room in this week's *Photographic News* for a hint on this subject.

I should mention exactly how I have been working

To the oz. of water, gelatine ... 2½ grains.

Collodion.

Pyroxyline 5 grains.

Bromide of cadmium 8 "

Alcohol, specific gravity about 830 ... 4 drachms

Ether 4 "

the collodion being mixed, one part made with a porous and rather structural collodion, the other two parts of a tough horny collodion, proportions in both cases as above; exciting bath 60 grains per ounce saturated with bromide of cadmium, first two washings distilled water, next hard water, and so on.

Begging you will kindly excuse my giving you so much trouble,—I am, dear sir, your obedient servant,

TYRO TANNIN.

Major Russell's explanation is as follows:—

DEAR SIR,—I shall be very glad to help your correspondent out of his difficulty if I can. I have never seen the fault which he complains of; but, from his description, I think it is caused by the gelatine swelling and penetrating the film of collodion, and perhaps leaving the glass. The following precautions will, I think, prevent the evil:—Dry

the plates well, either by heat or by standing separately for some time, after cleaning with old collodion to ensure adhesion of the gelatine to the glass; it may be known when they have been dried enough by the velvet rubber slipping easily over the plate; use very little acetic acid with the gelatine, and when this appears dry, finish the drying by heat to drive off all traces of the acid; this last precaution is particularly important in hot weather, to prevent solution of the gelatine during excitement. There appears to me to be too much water in the collodion; I should use either stronger alcohol or a larger proportion of ether. A rather larger proportion of the horny collodion, and perhaps a little less bromide, say seven grains to the ounce, would help to defend the gelatine. I have found bromized collodion to work well on a substratum of gelatine, but the film seems to be more permeable than when iodide is used, as the bromide of silver is formed more uniformly throughout the thickness of the film, and does not come to the surface like iodide during excitement; this circumstance is favourable in other respects, but renders a substratum of gelatine less applicable; I therefore prefer one of the following methods with this kind of collodion, especially for the alkaline developer; paint a very narrow strip of the surface near the edge of the glass very thinly with a solution of 2 to 5 grains of gelatine, in water, 7 drachms, alcohol, 1 drachm; for this purpose it is better to add nothing else. When the gelatine is dry the plate may be coated with collodion; or the edging of gelatine may be covered when dry by painting over in the same way with india-rubber and amber solution; or the whole glass, after being edged with gelatine, may be covered with the india-rubber and amber. This last is very easily done and answers well, if dust can be prevented from attaching itself to the india-rubber while drying. The india-rubber solution, if made with fairly pounded amber, should be allowed to stand and settle for some days, then, if decanted carefully, it will filter easily. Having been otherwise occupied, I have done nothing in the photographic way since April, until lately; and I found that the hot weather made some alterations in the way of working necessary. The bath required a considerable amount of acid; in cool weather a neutral one did well (the acid will act in the same direction as the high temperature in dissolving the gelatine), and the plates do not require to be kept so long in the bath; ten minutes I find enough for a highly bromized collodion in a 60-grain bath. The alkaline developer does not seem to work quite as well in hot as in cool weather, perhaps from want of sufficient acid in the bath. I forgot to say that if the glass is covered with gelatine solution, the liquid must be filtered immediately before pouring on each plate, as any clots would be likely to form transparent spots.—Yours very truly,

C. RUSSELL.

P.S.—I find the method which I have described in my new edition, of developing first with formic acid, and finishing with citric acid, to work remarkably well. Much acid is required in the developer in hot weather.

Romford, August 21, 1863.

Photographic Notes and Queries.

ROUGHING THE EDGES OF GLASS.

SIR,—Allow me to suggest to your readers the use of emery powder instead of silver sand as recommended by Major Russell in his excellent little book on the "Tannin Process," for grinding the margin of glass plates. It grinds much more effectually and evenly throughout, without chipping the corners of the glass.

I enclose a print, for your opinion, by tannin process.—I am, Sir, yours, truly,

THOS. R. LANE.

Sidney Place, Cork, Aug. 21, 1863.

[The print enclosed is very fine, indeed. Delicate, full of

detail, very brilliant, well-defined, and well-printed and toned. It only required a tint in the sky to make it perfect.—ED.]

SUCCESSFUL LIME TONING.

SIR,—The enclosed *cartes* are specimens of toning by Mr. Parkinson's lime process. I feel greatly surprised at reading accounts of failures from "Chameal-ion" and others. Nothing can be more simple, and no toning bath that I have used, or seen in my photographic career, gives such fine results as the lime one. A short time back I sent you a toning formula for Schering's paper. Although giving nice tones for albumen paper and working successfully, I have now thrown it aside. The reason I send you specimens is that you can quote me (if necessary) as one of the successful lime toners.—Yours respectfully,

DAVID DUNCAN.

Aug. 24, 1863.

GOLD TONING BATH WITH ACETATE OF SODA AND CHLORIDE OF LIME.

DEAR SIR,—I see Mr. Parkinson's letter in last week's paper mentions the use of acetate soda with chloride of lime and gold for toning. I have been using this bath, and believe it to be the very best I have ever tried. I keep my gold solution with a sediment of chalk in the bottle, and a saturated solution of chloride of lime in another bottle. To make my bath I put 1 grain of gold from the solution into 8 ounces water, and drop in 8 drops of the solution of chloride of lime. Then dissolve 40 grains, or 60 grains of acetate of soda, or potass, in it; put the solution in an open cup, and stand it in hot water about ten minutes; let it cool, and it is fit for use. Less chloride of lime might probably answer in place of heating it. It is certainly more manageable than either acetate soda alone, or chloride lime alone, and meanness seems banished. The enclosed prints were thus treated. I have lately built a glass studio after the plan of Mr. Matheson's somewhat, and find it answer admirably.—I am, Sir, yours faithfully,

WM. BARTHOLOMEW.

Egham, Aug. 24, 1863.

VARNISH FOR INDIA.

SIR,—I have just time before the mail leaves, to beg you to warn all Indian photographers against a hard spirit varnish made in England, apparently an imitation of Sohnee. I have just come down from the hills, where, as ill luck would have it, I ran out of varnish and bought a bottle. Every negative has become tacky, and some are useless.

A varnish for the tropics should stand an atmosphere at 90° saturated with steam for a week and then not be the least tacky. On the temperature rising in the sun (printing to 160° or 170°, negatives are often so hot that they blister one's hand. I believe lac (seed lac), in half spirits of wine and half alcohol, is a good varnish: it should be about 50 grains of seed lac to the ounce, and will then set when the plate is just warm. I have used this successfully and met no difficulties. I am now trying a formula given me by a professional, whose only fault is the great heat needed for setting it bright. I recommend all parties to get a good tried formula, and make their own varnish. It is cheapest, and I know none worth a straw in the market.—Yours obediently,

J. P. TENNANT, Major, R. E.

India, July 15, 1863.

Miscellaneous.

GUN COTTON.—Collodion is a viscid semi-transparent fluid, formed by dissolving pyroxyline (gun cotton) in a mixture of ether and alcohol. Pyroxyline is prepared by immersing cotton flax, unsized paper, or any substance composed of lignine in a mixture of nitric and sulphuric acid. In 1833 M. Braconnot discovered that, when starch was submitted to the action of nitric acid, it became converted into a peculiar substance, which dissolved in the acid, and was precipitated upon the addition of water. This substance, which was named, xyloidine, was found to explode when dry, at a temperature of 356°. The subsequent researches of M. Pelouze proved this substance to be starch, in which one equivalent of hydrogen was replaced by one of peroxide of nitrogen. In 1846 M. Schönbein discovered gun cotton

or pyroxyline, an explosive material, soluble in ether and alcohol. His method of making it was by immersing cotton in a mixture consisting of one part of nitric acid added to three of sulphuric acid. After being immersed for five minutes the cotton was washed repeatedly in water and dried. The sulphuric acid contained in the mixture was simply to absorb the water formed in the process, which would otherwise weaken the nitric acid and cause it to dissolve the pyroxyline. Chemists soon recognized the analogy of these two compounds, starch and lignine being similar in composition, and cotton fibre being nearly pure lignine. Further research proved that there were three principal varieties of pyroxyline, depending on the strength of the nitro-sulphuric acid used. By employing the strongest mixed acids the most explosive gun cotton was produced; it contained the largest amount of peroxide of nitrogen, and was only soluble in acetic ether. This was the quality most adapted for blasting operations. The second kind, made with a slightly weaker acid than the last, contained less peroxide of nitrogen, and was not so explosive, dissolved readily in ether and alcohol, and is now used for making collodion. The third form, made from still weaker acids, contained still less peroxide of nitrogen and was only combustible.

Talk in the Studio.

ROYAL PATRONAGE.—A few years ago, Charles Dickens specified having a photograph taken as one of the latter-day duties which should not be omitted. We are glad, for the sake of our art, to record that the reigning family of Great Britain are most exemplary and constant in their performance of that duty. Our readers who are familiar with the name of Mr. Jabez Hughes will be glad to learn that Her Royal Highness the Princess Louisa honoured him with another sitting at his studio a few days ago, when he succeeded in obtaining some excellent negatives.

FORGERY BY PHOTOGRAPHY.—Renaldi, the Swiss, who some time ago engaged a photographer named McGuire to forge, by photography, a one-gulden Austrian note, was recently found guilty. Mr. Sleight, in opening the prosecution, said:—The evidence would establish the fact that, for the first time in this country, the art and science of photography had been prostituted for purposes of fraud. It would be shown that a genuine note had been photographed on a piece of glass by a person named McGuire, under the direction of the prisoner, and that from that plate (had it not been covered with a coating to prevent its being so used), there might have been printed by a certain simple process thousands of notes, which would be more identical with the original note than any that could be produced by the tool of the engraver.

VALUE OF ARCHITECTURAL PHOTOGRAPHS.—In a report from the Council of the Architectural Museum, South Kensington, on the formation of a National Museum of Architecture, they remark, "It is impossible for an architectural museum to have too many photographs. Cheap and comprehensive as they are, they are always worth collecting, and any fastidiousness as to their acquisition would be misplaced. * * * There is hardly a new building now undertaken which is not photographed at the instance of the architect, or the employer, and an understanding might easily be established that it was expected that a photograph of every new construction, possessed of any architectural character, should be deposited in the National collection."

To Correspondents.

JAMES STODDARD.—We are not aware whether Mr. Pouncey has appointed any agent for the sale of his prepared paper; but it can be obtained direct from himself. A note addressed to him, at Dorchester, will find him. We do not know whether he will supply sample sheets.

LIME.—We do not know of any method you could adopt to secure an engagement in France, except by advertising. Possibly an advertisement in the *Moniteur de la Photographie* might aid you. The address of the publisher is M. Lieber, Rue de Seine, Paris. Mr. Parkinson recently needed assistance, but is supplied.

TYPO.—It is recommended that printing, toning, and fixing should be completed within twenty-four hours of exciting the paper, because, independent of the action of light, a slow decomposition goes forward when nitrate of silver and organic matter, such as albumen, are brought into contact or combination, which gradually deteriorates the colour of the paper. Under some circumstances, the excited or printed paper may be kept longer with impunity, but not usually. If you try to keep the prints a week before toning and fixing you will see the result. 2. If your new bath does not

work well it may proceed from two or three causes. It may arise from a slight amount of alkalinity, in which case the addition of a drop or two of nitric acid will remedy the evil. It may arise from impurities in the silver or distilled water, in which case, first add a little of a solution of carbonate of soda, sufficient to leave the bath turbid, and then expose it for a few hours to a bright sunlight, which will reduce any organic matter present. Then filter and try a plate. It will, probably, work well. If not quite clear in the shadows add a trace of nitric acid. 3. You cannot readily eliminate acetic acid from a nitrate bath. By boiling down the bath to dryness you may get rid of a great portion of it. By adding carbonate of soda you will form acetate of silver, and by reducing the temperature as low as possible a portion of this will be precipitated, and may be filtered out. Or, by sunning, a portion will be reduced, and may be filtered out. 4. Your prints assuming a feeble sandy colour in the printing frame, instead of a rich brown or purple, suggests that a silver bath is getting weak. Add more silver to it. M. A.—You will find an interesting article on printing in skies by Mr. Noverre in our number for April 10th of the present year. Also in Nos. 115 and 156, by Mr. Samuel Fry, and in 157, by Mr. Maxwell Lyte. The subject has been incidentally treated in other articles, but these will probably serve your purpose.

AMENIA ASKS.—Would any of your readers give me the address of the following firm in Germany:—Anstalt v. Otilie Wigand.

A RECENT SUBSCRIBER.—Col. Stuart Wortley gave full details of his operations in producing his fine instantaneous pictures at a meeting of the Photographic Society this year. You will find his paper in the *Photographic News*, Feb. 13, 1863. We agree in your remarks on the importance of clouds; the subject has been repeatedly treated in our columns, and will probably be again shortly.

R. RODGERS.—By careful working you may secure an angle of about 40° with a single landscape lens; but not much beyond that, especially in architectural work, which readily shows the distortion. 2. Distilled water purified with permanganate of potash may be used for photographic purposes. There should not be excess of permanganate, so soon as the water shows the faintest trace of permanent colour it has had sufficient. 3. The effect of all varnishes is to add slightly to the transparency of negatives, and thus slightly reduce the intensity. A very dilute varnish which will glaze the shadows and let the lights dry dead, will do this in the least possible degree. 4. We cannot tell you how to obtain good specimens of card pictures except by selecting from those which are published for sale.

AN AMATEUR SUBSCRIBER.—Your negative is a little under-exposed and over-developed, or over-intensified. With a better negative, deeper printing, and longer toning you would get the colour you desire, with the same toning bath.

T. SANDENS.—M. Disderi does not, so far as we know, use the lime and gold toning bath.

W. H. B.—The tone of the print is very good, but it is not desirable to need such a prolonged immersion to obtain it. 2. The printing is good, but the negative is faulty, being over-intensified, and the figure very stiffly posed. 3. There are generally engagements open to good photographers, the remuneration varying very much, just as the degrees of ability vary. 4. We are glad to learn that your lens is a good one. The definition of the print is very satisfactory. We shall be glad to see specimens of your progress.

ARCHITECTURAL STEREOGRAPHS.—We are requested by Messrs. Dutton to state that the stereographs of churches in Bristol and Bath, noticed in our last, were produced with Ross's single stereo lens of 4½ inch focus. The definition is excellent, but the curvature of marginal lines, inseparable from the single lens, is in some instances very apparent. The use of a double combination is preferable for interiors and all architectural work.

AL FRESCO.—So far as the open air lighting is concerned your pictures are not bad; the posing is also pretty good. A little longer exposure would have been an improvement and a little lighter printing. The toning effected in your lime bath is most satisfactory.

F. N.—The objection to the use of iodide of iron consists in the fact that the collodion does not keep well when prepared with it, and is apt to injure the bath. Its use certainly gives rapidly, and it is possible that further experiments would repay the student.

J. M. PRICE.—We are glad to learn that you have found your globe lens so satisfactory, and should have been glad to have had a more detailed statement of your experiments. You mistake altogether in supposing that we have any wish to disparage the lens in question. We readily admit the good points it possesses—such as embracing a wider angle than the single lens, being free from distortion, and giving great depth of focus; but it does not include the angle claimed for it, namely, 90°; and its depth of focus is the result of spherical aberration, and there is a consequent loss of crisp definition. In our estimation, so far as we have examined the lens, or seen its work, it is not equal to the triple for general use. The Americans compare it with the old lenses, but ignore the triple altogether.

Several articles in type, amongst which is one on the new method of "Transferring the Film from the Albumenized Paper to Porcelain," &c., stand over until our next.

Several Correspondents in our next.

TRANSFERRING THE IMAGE FROM ALBUMENIZED PAPER TO PORCELAIN, ETC.

WE have just successfully completed some experiments with a new process for the application of photography to ornamental art, which promises very pleasing results, and will interest many of our readers. It consists in transferring the film of albumen on which is impressed the photographic image from a negative on to a vase, jar, or other surface of porcelain, enamelled glass, &c., in which position it is seen either as a direct positive or a transparency. The process originated in the establishment of M. Beyrich, of Berlin, and is due, we believe, to M. Grüne, a chemist in his establishment. Our attention was first called to the subject by Mr. J. W. Osborne, who is at present residing at Berlin. In a letter received a couple of months ago, he says:—

I have visited Beyrich's factory, and have been received in a very friendly manner. Mr. Grüne, the chemist there, is at present engaged in perfecting a new description of positive paper, by which photography can be transferred to any surface curved or flat, and of metal, wood, glass or porcelain, indiscriminately. This paper is so constituted, that after the printing and toning has been effected upon it by the ordinary methods, the whole film of albumen is made to detach itself from the paper, and to swim freely in a large quantity of water. The article to receive the photograph, is now brought under the film and lifted from the water with the picture in the desired position upon it, or nearly so, for it admits of perfect adjustment with the fingers. When dry, the film adheres with great tenacity to any smooth surface, and after a coat of varnish has been applied, it is in a condition to resist a moderate amount of washing and rubbing. I shall have more to tell you about this matter and many others, which have come under my notice here. For the present, I must defer sending you the paper, but am able through the kindness of Mr. Grüne of the firm above named, to forward you by an Australian friend who leaves Berlin for London this week, two or three specimens which will serve to illustrate what has been accomplished. As far as I can judge, the whole of the operations are perfectly simple, and I believe the process will be found a useful one for ornamenting many articles of luxury or comfort.

The examples referred to never arrived; but we saw one or two specimens of ornamented vases sent by M. Beyrich to the French Exhibition, which were very beautiful. A few days ago, the Hon. Nassau Jocelyn, secretary to the British embassy at Berlin, an able and enthusiastic photographer, and esteemed correspondent of THE PHOTOGRAPHIC NEWS, sent us two charming pictures transferred in this way on to opal glass, and placed in ornamental frames, with supports, to allow them to stand in a position which permits them to be examined either by transmitted or reflected light, as ordinary positives or as transparencies. They are beautiful as ordinary positives, but still more so as transparencies. Being printed on albumenized paper, and toned in the ordinary manner, the tone and general character of the image may vary from the effect of a sepia drawing to that of an engraving. The most pleasing tint is a warm sepia or delicate purple; these before us have the former tone.

The instructions we have received from Mr. Jocelyn are as follows:—

The paper (resembling ordinary albumenized) is silvered as usual, but *very* much over-printed from the negative, in fact, till the lights are quite gone, and the print appears lost. It is then washed to free from silver, and toned, and then rinsed.

While rinsing, the print may be observed to be covered with blisters. These gradually increase in size until finally the delicate film of gelatine upon which the picture is, splits off and floats into the water.

It is then very carefully placed in hypo, and then well washed—every washing appearing to render it more tough, till at last it may be handled with impunity.

The glass, or porcelain upon which it is to be placed is then passed under the film, and both lifted out of the water together. When dry, it is trimmed, and covered with transparent hard varnish.

We have also received from Messrs Harvey, Reynolds, and Fowler a sample of paper for producing these pictures, prepared, we presume, by M. Beyrich. As the instructions they forward vary slightly from those just given, and contain one or two additional hints, we repeat them also.

Excite the paper as for albumenized paper. Dry. Print *very* deeply, you can scarcely print too deep. Tone as albumenized paper, more care will be required as the prints are over-printed, and the changes of tone are not so readily observed. Wash in water. A film now begins to leave the paper. Pass into the hypobath one part in five. The film now entirely separates from the paper, and the paper must be removed. Let the film remain in the hypo about ten minutes, and then carefully and thoroughly wash in water. The film is now very elastic.

To transfer this film on to any surface: *well* clean the surface, and bring it under the film which is floating on pure water. Raise both out of the water together, pull the film into the desired position on the object, and let it dry. Then varnish with a clear varnish. If the film should not adhere as closely as desired on round surfaces, wash it (without removing it from the object) with a mixture of 1 part acetic acid 32°, and 6 of water. As soon as it becomes elastic, wash with water, and it will adhere well.

As the manipulations thus described seem to present some difficulties we were anxious, prior to bringing the process before our readers, to put it into practice. We have accordingly exposed half a dozen pictures and transferred them according to instructions. We have succeeded beyond our expectations, and have obtained, at the first attempt, some very pleasing transfers. We will briefly detail our proceedings.

The paper was excited on a sixty-grain bath, and a couple of pieces exposed under a portrait negative, until the highest lights were of a lavender tint. This we subsequently found was not quite deep enough. The prints were washed and toned as usual, reaching a deep purple in the gold bath, which was one made after Parkinson's formula. On being transferred to a dish of water, and washed well, we did not observe either blistering or entire separation of the film as

expected. We then transferred them to the hypo bath, and allowed them to remain a quarter of an hour. A slight blistering was now apparent, which increased in the subsequent wash of water. But as the separation did not take place so speedily as we anticipated, we added a trace of carbonate of soda to the water, and in a few minutes we saw the delicate transparent film separated from the paper, and floating in the water. After rinsing we placed a piece of white enamel glass underneath the floating film, and by a little careful management, lifted it from the water, uninjured and stretched flat upon the glass, where it dried, smooth, bright, and firm. We now exposed a couple more, and printed until the image was completely buried, after which, before toning, we trimmed the print to the shape we desired, as we found it was a difficult thing to shape the film when once detached from the paper. We toned this time in a bath containing a little carbonate of soda, and we observed in the subsequent rinsing, that the blisters began to arise; these increased in the hypo bath, and in the course of the subsequent washings, the film readily separated and floated away from the paper. A subsequent couple were toned in the lime bath, washed, and fixed. These also separated in the subsequent washing without any trouble; but a longer time was necessary, some hours elapsing before the film of albumen was quite detached.

Some care and skill in manipulation are necessary in getting the film in proper shape, and into the proper position on its final resting place. The attenuated film, as delicate as the wing of the smallest fly, at first sight seems quite unmanageable, curling, twisting, and folding itself with the slightest disturbance of the water, and if the object on which it is to be placed be brought under it, and both lifted out of the water without proper precaution, it will probably be found to have run up together into a shapeless mass, apparently beyond remedy. If it be carefully returned to the water, the probability is that it will gradually float straight out again, and present itself quite uninjured. A little care and patience will be required. Our second attempt was to transfer the film, which had previously been cut when on the paper, into a medallion, on to a cylindrical vase; and using a little care and tact, we succeeded perfectly. The film was placed in a large basin of water; the vase was introduced under it, and brought carefully into the right position. It was then lifted carefully, so as to avoid making a wave in the water, which would have sent the film floating away, turning somersaults in the most tantalizing manner. The film, although so slight, is very tough, and admits of a little careful readjustment; but is very easily stretched out of shape, and should be as little handled as possible. After it is fixed in its place and dry, it may be trimmed, if necessary; but it is better to cut the print to the desired shape when it leaves the pressure frame.

The variety of ornamental purposes for such transfers will readily suggest themselves. When transferred to plain white enamel glass, the pictures acquire not only a beauty as transparencies, but also as positives, which they did not possess before. The pure white and fine surface seems to impart a wondrous charm of delicacy and brilliancy altogether unexpected, which, for locket and brooch portraits, will possess especial value. It is probable that the film so transferred to ivory will be of value to the miniature painter. As ornaments for vases of opal glass, &c., many very beautiful effects may be produced. In the art of diaphanie, and as an adjunct to the now fashionable art of decalcomanie, it will probably be found useful; and in a variety of ways which do not now occur to us. At present, the only protection is a hard varnish, but it is possible that by the use of an enamel powder fusing at a low temperature, a vitreous surface might be secured.

One or two cautions, arising out of our experiments, we may suggest. If the film be transferred to plain glass flashed with a white enamel, take care that it is to the flashed side that the film is attached, otherwise, as will be readily seen a very imperfect result is produced. Avoid the

use of a ground or unpolished surface, as the film is apt to crack on drying when attached to such a surface. A little carbonate of soda will aid the separation of the film from the paper, but it is better to have patience, and let it be effected by time. The film appears to rest on some coating applied to the paper, and which is soluble in water, and may be seen to diffuse itself therein. It is but a question of time, therefore, to secure entire solution.

The process affords singular facility for observing certain facts in regard to the nature of the image on albumenized paper. It is to be noted that when the film of albumen is removed, a perfectly defined image is found on the paper underneath. It is also to be noted, as confirming the conclusions of Mr. Spiller, and contradicting those of Dr. Schnauss, that whilst the colour of the image on both sides of the film may be the rich purple of gold, the image underneath, on the paper, is of the foxy red of an untuned silver print.

British Association for the Advancement of Science.

THE meetings of the British Association just concluded at Newcastle on Tyne have been, in some points, perhaps, the most successful which have ever been held. The number of members and of associates enrolled, and the funds collected have, we believe, exceeded those of any former occasion. The works of art collected in the Exhibition, got up in connexion with the Association, were unusually fine and interesting. The excursions to the scenes of various important industries were numerous and inviting. Many of the subjects brought forward were interesting and ably treated. The inhabitants of the town and district were enthusiastic and hospitable. But with all this, we cannot rid ourselves of the impression that there was a great deal of mismanagement in various respects. However little the inhabitants generally are answerable for the fact, it does not tend to enhance the reputation of the town, that the hotel keepers should seize the occasion when the town is honoured with an especial influx of scientific visitors, to fleece their guests: in some instances, we believe, increasing their regular tariff two hundred per cent. It does not tend to improve the reputation of the Association, that, after a paper has been examined and accepted by the committee of a section, the chairman should brusquely tell the reader when he has just commenced to read, that his paper was of a nature which cannot be received. It is, however, easy to find fault, and we are, perhaps, the more ready to be imperfectly satisfied, from the fact that no former meeting for some time was so barren of photographic interest as the present. There was no properly photographic paper of any kind read, and not many at all connected with photography. Our art-science, in fact, has scarcely a home in the Association. It vibrates uncertainly between section A, Mathematical and Physical science, and section B, Chemical science. We look forward to the day when a section shall be devoted to photography and its various branches; and when greater temptations and facilities for bringing it forward shall be the inducement to many gentleman to bring forward matters of interest, which are at present undisputed at the Association.

The meetings commenced on Wednesday, the 26th ult. The address of the President, Sir William Armstrong, was marked by strong practical common sense, and was of a popular rather than of a recondite or elaborate character. No recognition was made in it of photography as one of the great discoveries or wondrously progressing powers of the day, although an art less popular, if not less important—photography—received more than a passing notice. Much, however, of the able speech of the President dealt with the agencies, every detail in connection with which is interesting to photographers. The startling fact, that the sun is the

great source of power and motion on the earth was admirably pointed out, especially in its relation to the production of coal. "That small pencil of solar radiation," he remarked, "which is arrested by our planet, and which constitutes less than the 2,000-millionth part of the total energy sent forth from the sun, must be regarded as the power which enables the plants of the carboniferous period to wrest the carbon they required from the oxygen with which it was combined, and eventually to deposit it as the solid material of coal. In our day, the reunion of that carbon with oxygen restores the energy expended in the former process, and thus we are enabled to utilize the power originally derived from the luminous centre of our planetary system." His further glance at the nature of the sun is worthy of quoting:—

"In the course of the preceding observations I have had occasion to speak of the sun as the great source of motive power on our earth, and I must not omit to refer to recent discoveries connected with that most glorious body. Of all the results which science has produced within the last few years, none has been more unexpected than that by which we are enabled to test the materials of which the sun is made, and prove their identity, in part at least, with those of our planet. The spectrum experiments of Bunsen and Kirchhoff have not only shown all this, but they have also corroborated previous conjectures as to the luminous envelope of the sun. I have still to advert to Mr. Nasmyth's remarkable discovery, that the bright surface of the sun is composed of an aggregation of apparently solid forms, shaped like willow-leaves, or some well-known forms of Diatomacea, and interlacing one another in every direction. The forms are so regular in size and shape as to have led to a suggestion from one of our profoundest philosophers of their being organisms, possibly even partaking of the nature of life, but, at all events, closely connected with the heating and vivifying influences of the sun. These mysterious objects, which, since Mr. Nasmyth discovered them, have been seen by other observers as well, are computed to be each not less than 1,000 miles in length and about 100 miles in breadth. The enormous chasm in the sun's photosphere, to which we apply the diminutive term 'spots,' exhibit the extremities of these leaf-like bodies pointing inwards, and fringing the sides of the cavern far down into the abyss. Sometimes they form a sort of rope or bridge across the chasm, and appear to adhere to one another by lateral attraction. I can imagine nothing more deserving of the scrutiny of observers than these extraordinary forms. The sympathy also which appears to exist between forces operating in the sun and magnetic forces belonging to the earth merits a continuance of that close attention which it has already received from the British Association, and of labours such as General Sabine has with so much ability and effect devoted to the elucidation of the subject. I may here notice that most remarkable phenomenon which was seen by independent observers at two different places on the 1st of September, 1859. A sudden outburst of light, far exceeding the brightness of the sun's surface, was seen to take place, and sweep like a drifting cloud over a portion of the solar face. This was attended with magnetic disturbances of unusual intensity and with exhibitions of aurora of extraordinary brilliancy. The identical instant at which the effusion of light was observed was recorded by an abrupt and strongly marked deflection in the self-registering instruments at Kew. The phenomenon as seen was probably only part of what actually took place, for the magnetic storm in the midst of which it occurred commenced before and continued after the event. If conjecture be allowable in such a case, we may suppose that this remarkable event had some connection with the means by which the sun's heat is renovated. It is a reasonable supposition that the sun was at that time in the act of receiving a more than usual accession of new energy; and the theory which assigns the maintenance of its power to cosmical matter plunging into it with that prodigious velocity which gravitation would impress upon it as it approached to actual contact with the

solar orb, would afford an explanation of this sudden exhibition of intensified light in harmony with the knowledge we have now attained that arrested motion is represented by equivalent heat."

Our space does not permit us now to give all the sectional papers which may interest our readers; but we hope to do so in our next. In the meantime we may glance at what was done at all interesting to photographers. On Wednesday the Report of the Kew Committee was read; it presented many interesting illustrations of the aid photography is lending to the sciences of astronomy, magnetism, &c. On Thursday Mr. Claudet read an interesting paper on "Some Phenomena produced by the Refractive Power of the Eye." On Friday the same gentleman read a paper on "The Star Chromascope;" Mr. B. S. Proctor read a paper on "The Focal Adjustment of the Eye;" and the Abbé Moigno exhibited and described an instrument invented by M. Soleil, called the Tenebroscope, for showing that light itself is invisible. On the same day, in the Chemical Section, a very interesting report on gun-cotton was read, describing and illustrating by experiment its superiority in many respects over gunpowder. On Saturday, in Section A, Professor C. Piazzi Smyth exhibited some of his photographs taken on Teneriffe, at an altitude of 10,700 feet, of a landscape four miles and a half distant, and pointed out the perfect and clear rendering of detail as an illustration of the more perfect actinic conditions at a high elevation. One of the specimens exhibited was a photographic engraving, the latest result of Mr. Fox Talbot's experiments in photoglyphy, a decided advance upon former attempts.

On Monday, in the same section, Mr. Stewart read a paper on comparisons of curves afforded by the photographic self-recording magnetographs, at Kew and Lisbon. In the same section, on Tuesday, Mr. Swan read a paper, "A new kind of Miniature, possessing apparent Solidity, produced by means of a Combination of Prisms." Mr. Swan's paper, which appears in another page, describes a most ingenious application of the stereoscopic principle. Two triangular prisms are placed in such a position as to form one cubical prism. Two transparent positives, taken at the proper stereoscopic angle, are mounted in such a manner that one is seen directly through the cube, and the other by reflection from the face of the prism, the two images being thus superposed and giving perfect relief. The specimens exhibited were neatly mounted in morocco cases, and in gold, to be worn as charms, &c. They are backed by opal glass, and some of them coloured. The result is as pleasing as the contrivance is novel and ingenious.

In section B, a paper by Mr. Dallas was announced, on Photo-electric Engraving and Observations on Photographic Engraving. As the whole details of the process were not to be given, the chairman thought the paper inadmissible. We shall, however, print it in full, or in abstract. The Abbé Moigno exhibited some fine photolithographs, by M. Marquier, and made a few observations on the method. He also exhibited some micro-photographic specimens mounted in rings, &c. Dr. Phipson read a paper on a new method of measuring the chemical action of the sun's rays. These complete the papers which had any photographic interest or bearing.

Photographs were frequently used to illustrate papers in the various sections, and at Mr. Glaisher's lecture on ballooning some very clever photographs were exhibited, produced by Messrs. Negretti and Zambra, showing Mr. Glaisher with his instruments arranged, together with Mr. Coxwell in the ear of the balloon, which appears to be just entering into the clouds, and leaving the earth dark and indistinct beneath. The picture is produced by the combined aid of photography and art. The ear and its occupants were photographed whilst the balloon was held to its moorings, and the background and other effects painted in with very clever effect.

The soirees, lectures, balls, &c., were unusually attractive and crowded. In the Central Exchange News-room a very fine collection of works of art and science was exhibited.

Amongst these were comprised a splendid collection of oil paintings and water colour drawings by great artists, contributed by various gentlemen in the neighbourhood. Fine specimens of the natural products and industrial arts of the district. Curiosities natural and artificial. Rare ores and metals, amongst these being an ingot of thallium, by Mr. Crookes, weighing a quarter of a hundred weight. Various beautiful specimens of aluminium bronze, amongst these being a specimen of M. Willeme's photo-sculpture, in the shape of a full-length statuette of M. Emile Percire. Microscopes and objects by Ross and others. With the exception of some solar camera enlargements by M. Claudet, and some enlarged copies of the moon, by De la Rue, we did not observe any photographs exhibited. This omission was partly due to want of space and partly to the difficulty experienced on such occasions to draw the line satisfactorily between what is interesting to the public and what is simply sent for advertising purposes. Altogether the Exhibition was a most interesting one, possessing more valuable contributions than generally find their way into local exhibitions.

ON THE PRODUCTION AND USE OF CLOUD NEGATIVES.

BY V. BLANCHARD.

THE great stride made by landscape photography during the past few years is now fully admitted. Those, even, who were most doubtful that photography would ever make or maintain a position among the fine arts would scarcely deny that the landscape productions of to-day show an undoubted advance upon the black and white patches produced a few years ago and called by courtesy *photographs*.

But with this marked improvement of the last few years has risen also the standard of criticism. We get now something like atmosphere into our best landscapes, but they will be *perfect* only when produced instantaneously, so as to secure *all* the effects visible to the eye of the camera at the moment when the picture is taken. Pending the arrival of this "good time coming," when it will be possible to produce landscapes of any size instantaneously, no matter how trying the subject, we must be content to do the best with the means at hand; and as white paper, in place of atmosphere, is now an abomination, the only plan left is to print the blank surface with something that shall bear resemblance to nature, sufficient at least to make it passable.

The printing in of clouds from separate negatives is not without some difficulty, but with ordinary care results can be produced sufficiently true to nature to be pleasing to the general eye. The best effect, of course, can only be produced by taking the cloud negative just immediately before or after the landscape one. But here comes the great difficulty. The days most suitable for the landscape photographer, who perchance is working with dry plates and is compelled therefore to give one, five, or ten minutes, are those when Boreas and Sons have taken holiday and have gone to the sea side for a change, and when, in consequence, all nature assumes an air of listlessness; the trees even are too idle to shake their thin leaves or sway their heads. These days so earnestly looked for by the landscape photographer, so few and far between—for even the elements believe in work in England—are just the days when the clouds are absent with a ticket of leave, to join company with Boreas and family, they being inseparable companions. The photographer is compelled, in spite of himself, if he desire to fill up the nakedness of his sky, to print from some negative foreign to the scene, and whilst the result so obtained will be pleasing to many it will never quite satisfy the eye of the close observer of nature. It can easily be said that the picture will be quite as true as the great mass of landscape paintings, which are invariably the results of a number of separate studies. This will, however, be but a poor apology, for when we examine the works of Turner or Stanfield and then turn to our best instantaneous productions, we see there caught at

once; many of those atmospheric effects, which cost them a lifetime of patient study, with all the appliances of colour to aid them in their efforts, and then only imperfectly rendered. An examination of almost any instantaneous picture will at once show that there are a thousand little points of detail that only such men as Turner, and a very few others, have been able to indicate. The long trail of smoke from some steamboat, like an immense dusky snake slowly unwinding his gigantic coils over the scene, but with the shadow also blotting out the sunlight wherever it falls. The sea mist coming up veiling one portion of the picture in gloom and indistinctness, while the other part stands with preternatural sharpness, that every little cloud scudding rapidly across the sky is faithfully represented in the scene below by its corresponding shadow; all these, and a thousand other effects, are caught in the instantaneous picture, and cannot possibly be rendered where the exposure is long, and where the clouds are printed in separately. It will at once, then, be apparent that great judgment is needed in using cloud negatives, and that they cannot be used indiscriminately without producing pictures open to very serious criticism.

The most beautiful studies of clouds are produced when the camera is pointed towards the sun, for greater contrasts of light and shade are seen. Cloud negatives so taken, however, can, unfortunately, seldom be used, for in landscape photography the operator is not often so daring as to work with the light in front, and of course such negatives can be used only when the landscape is thus lighted. Care must also be taken to choose an open space with no objects to break the horizon line. The sea side is best for this purpose. The grand banks of cumulus clouds are best to photograph, and are most effective, but care must be taken not to get them too large, otherwise the want of corresponding shade in the landscape will be painfully felt. Some of the very best clouds are to be seen when the sun is obscured, for they are generally of various shades of grey, and in consequence are more manageable; but care must be taken to print them in very light, or it will be seen at once that there is no sunshine on them. Contrary to what might have been expected, no great care or extra preparation is needed to procure clouds; any bath in good working condition will do. The stop in the lens should be moderately small, and a landscape lens will be found better as a rule than a double combination. The time should be as nearly as possible the same as that chosen for the negative, for nothing could be worse than to use clouds taken in the evening, when the sun is low, for a picture taken at 12 at noon. The exposure for cloud negatives will vary slightly with the amount of light, but, as a rule, the focussing cloth taken off the lens and back again as rapidly as the hands can execute the operation will prove about the necessary amount of exposure.

Some considerable degree of judgment will be needed to know the clouds best suited for the purpose, and a number of failures may be expected. There are many clouds most agreeable to the eye that will show no relief when taken, and much disappointment will be avoided by studying form rather than colour. The collodion best suited for the production of clouds is one favourable to intensity to begin with, and should be of a deep sherry colour, and if not so to begin with, may be made so by the addition of a few drops of tincture of iodine. The developing solution should be about 15 grains to the ounce, and should contain rather more than the usual quantity of acetic acid, say 20 drops to the ounce, for it is necessary to have the shadows as transparent as possible. The negative will not need to be dense, therefore, very little, if any, intensifying will be needed. A little pyro, with a few drops of silver added, poured on and off a few times, will be sufficient. If the surface is just darkened, it will be found sufficient.

In printing from the negative it will be found best to print the clouds first, care being taken to cover up with cotton, wool, and paper, as nearly as possible, all the parts

required for the landscape. If a few trees, or any dark object rise up into the sky, no notice need be taken of them, for the slight staining of the paper from the cloud negative will be completely lost in the after printing from the negative.

It will be found a capital plan to put a piece of cardboard, slightly curled upward, outside the pressure frame containing the cloud negative, taking care that all the parts required for the landscape are covered. If this be printed in the shade, and the curled edge of the cardboard be towards the sky, the light will subdue itself under the curled edge, and will so produce that softening towards the horizon so necessary to make a success of this method of double printing.

By means of an enlarging camera, it would be possible to make negatives from stereoscopic ones that would serve for all kinds of pictures. An enlarged transparency would have to be made, and then from it the negative could be produced of any dimensions necessary to suit the requirements of the picture.

For those who have no cloud negatives, nor the time to watch for the suitable opportunity to produce them, there is a very simple plan for getting rid of the white paper sky, and materially improving the appearance of the picture. It is, indeed, so simple that an apology is almost needed for mentioning it in these pages; but there may be some who have never heard of it, and to whom the idea may never have occurred, therefore it shall be described. After the print is taken from the pressure frame, lay it on a large book, and take a piece of cardboard larger than the picture, and move it slowly up and down, taking care that the picture positive is always covered. Of course, this operation must be performed in a good light. It may be done in sunlight, but greater care is needed. The sky will be found, on examination, to have darkened down towards the horizon in an uniform manner, giving the picture very much the appearance of an Italian sky. Care must be taken, however, not to overdo it, or the sky will look heavy and muddy. Indeed, just the reverse of the desired effect will be produced.

We regard the plans here suggested as imperfect remedies for the cure of that great eyesore, a blank paper sky, and to be used only for want of something better, but fervently trust that the day is not far distant when the optical and chemical aids to photography will be so far perfected that instantaneous pictures will be quite easy on dry plates of any size.

PHOTOGRAPHY IN AUSTRALIA.

BY PAUL RICOCHET.*

WHILE in Hobarton, I had heard a great deal about the beauty of the scenery round Lake St. Clair; and the descriptions I had listened to, induced me to make up my mind to go there.

Now, in the old country, when a man makes up his mind to go any whither, he has merely to pack his bag, consult his Bradshaw, order a cab and take his ticket; but here, in Tasmania, the case is very different.

I discovered that for my expedition to Lake St. Clair, many things were needful, inasmuch as the latter part of the journey being through an almost uninhabited district, would necessitate camping out at night, and a proper supply of provisions.

Fortunately, a friend, who had been there before, declared he would accompany me, and with his assistance, and that of my servant, Mr. O'Corcoran (who knew no more what to do than myself) all requisites, including a horse and light, but stroug, spring cart to carry everything, were at length collected, and we took our departure, amid the sympathizing adieux of many friends.

The first twenty miles of our road lay beside the left bank of the Derwent, which, appearing and disappearing among

the hills, formed as it were a series of lakes. It was too late in the afternoon to photograph these "morceaux" satisfactorily, and we hastened on to New Norfolk, a township twenty miles up the river, which we reached at 10 o'clock in the evening.

Here we supped sumptuously on fresh-caught mullet, and the next morning started again on our pilgrimage—my friend Stedley and myself marching behind the cart, which O'Corcoran sitting in, drove solemnly, at the rate of three miles an hour.

In this way we traversed some eight or ten miles of a picturesque country, and arrived at the township of Hamilton, on the Clyde, about mid-day. After a halt of two hours, during which I photographed some falls at the junction of the Clyde and Derwent, we resumed our journey, reaching the village of the Ouse at nightfall. The next morning I got a fine view of the bridge over the rock-broken torrent which gives its name to the village.

Leaving the Ouse about 11 a.m., a steady walk of some twenty-two miles brought us to the foot of the Victoria Tier. In former days of the colony, there was a small settlement on the ridge of these hills, but it is now abandoned, and here, in consequence, we had our first night's camping out.

A grassy glade, near a water-hole, surrounded by thick tea-tree "scrub," was chosen as the spot to build on, and, having tethered our horse within reach of the water, we manufactured a tent of blankets stretched on green poles, and floored with tea-tree boughs, on which were laid our opossum-skin rugs.

A blazing fire was soon sputtering in front of the tent, and our kettle sang cheerfully as Mr. O'Corcoran prepared the supper, in which we all joined with keen appetites. Supper over, each man rolled himself in his rug, and, pipe in mouth, and something hot at elbow, we chatted and smoked till bed time.

The next day we reached Marlborough. At Marlborough I saw a strange sight. For miles round the settlement the ground is covered by a dense forest of lofty trees, every one of which is dead! Years ago, a severe frost came, and in a single night blighted them all, and there they stand—grey, ghastly, whitened skeletons. Through this forest a small river, the Nive, flows past Marlborough. It looked desolate in the extreme, with its banks naked and unclothed by a single green leaf.

The stream divides what the colonists call the "New Country," from the settled districts of the island. From Marlborough to Mount Charles, where there is a shepherd's hut, is about fourteen miles. We arrived there about three o'clock the following afternoon.

Mount Charles is close to Lake St. Clair; and, after a hearty dinner of chops, with "damper" (bush bread) and tea, we took one of the shepherds as guide, and walked to the lake. We found a convenient spot for a camp, and soon made things comfortable. I got the camera, &c., ready for a busy day's work on the morrow, and my friend Stedley occupied himself in cleaning a double-barrelled gun, wherewith it was his intention to shoot some of the black swans which abound on the lake.

The next morning I started along the shore of the river Derwent (which issues from Lake St. Clair), and managed to get a fine view of the picturesque rapids close to the entrance of the river. Two or three hours passed very pleasantly. I exposed plate after plate, as the views were endlessly varying, and everywhere charming; the lake itself is a grand sheet of water, and the thick, sombre woods grow close along the margin, here and there varied by a rocky beach, or sometimes a cliff, with tall, celery-topped pines hanging along the summit, and reflected finely in the deep black water below. As an experiment (having plenty of plates), I exposed one picture for thirty seconds, and a second plate at the same view for two minutes, intending to try whether by different methods of development an equal result might not be obtained in both cases. By the way, in case any of my

* Continued from p. 213.

readers should think the exposures rather scanty for collodio-albumen plates, I may here mention that the view in question was well lit up by the sun, and that the instrument used was a binocular stereoscopic camera, with double combinations. What degree of success I had will appear hereafter.

As I was returning to the camp after my operations, and passing by a number of tall reeds growing into the water for some distance, I heard the sudden report of a gun, followed by a direful howl and shout of anguish from the reeds—"Ach! Mother av Moses; Oi'm shot did—Oi'm shot did!" Hastening towards the sound, I discovered Mr. O'Corcoran "in a state of innocence" sitting in the shallow water and fervently invoking every saint in the calendar. The fact was, he had gone for a bathe, and Studley, who was on the other side of the reeds, and did not notice him, fired at a swan, and hit O'Corcoran by mistake. On examining him, however, we found the shot had hardly left a mark—it had, luckily, come too far to do serious damage.

After three days spent in photography round the Lake, we returned to Hobarton, and I set to work to develop my plates. On the journey, I had carried them in an air-tight tin box with grooves, changing the plates each evening by the firelight.

The first I developed were those exposed at the same view, one thirty and the other a hundred and twenty seconds. Moistening the first one thoroughly, I put it on a carefully levelled stand, and covered it with plenty of the following solution. Pyrogallie acid, $\frac{1}{2}$ grain; glacial acetic acid, 1 drachm; distilled water, 1 ounce; 20-grain solution of nitrate silver, 2 drops. In about four hours the details were slightly visible, and I then poured off the developer, washed the plate carefully, placed it in water at about 120° or 130° F., and then completed the development with a warm solution of pyrogallie acid, $1\frac{1}{2}$ grain; glacial acetic acid, 15 drops; distilled water, $\frac{1}{2}$ ounce; adding 20 grains solution of nitrate silver as required.

In this way the details were perfectly brought out, with fair contrasts of light and shade, and no tendency to reduce harshness from under-exposure.

The other plate (exposed two minutes), I developed in the usual manner, with pyrogallie acid, 2 grains; glacial acetic acid, $\frac{1}{2}$ drachm; distilled water, 1 ounce; adding nitrate of silver as required.

When finished, few people could tell the difference between the two pictures.

The other plates also turned out for the most part satisfactorily, some few were failures; but on the whole I had reason to be well satisfied with my success.

Besides my excursion to Lake St. Clair, I made many other journeys among the scenery of this beautiful island. Sometimes successful, at other times failing, always satisfied at gaining fresh experiences, I passed many pleasant weeks wandering with the camera among its mountains, its lakes, and its rivers; meeting, wherever I went, with kindness and hospitality alike from all classes of people. Since my return, I have always looked back to my trip to the colonies as one of the pleasantest years of my life, and my advice to a brother photographer who does not mind a long voyage, is, "Go and see Tasmania."

PAUL RICOCHET.

TANNIN NEGATIVES FOR ENLARGEMENT.

BY M. JULLIET.*

M. LACON, in giving M. Juliet's method in *Le Moniteur* remarks, that the latter gentleman, who is an operator in the photographic establishment of M. Ferric at Mans, has for a long time been engaged in very successful enlargement, using the solar camera (we presume Woodward's, misspelt Woodhoard) and the heliostat of Leon Foucault. The best

* *Moniteur de la Photographie.*

conditions of amplification, as regards apparatus being secured, it is to the quality of the negative he gives special attention, regarding excellent results as depending mainly thereon. For obtaining his negatives, he uses the tannin process; the details of his method follow:—

Collodion.

Alcohol	4 $\frac{1}{2}$ ounces.
Ether	6 $\frac{1}{2}$ "
Gun cotton	40 grains
Iodide of ammonium	25 "
" cadmium	15 "
Bromide of ammonium	2 $\frac{1}{2}$ "
" cadmium	2 $\frac{1}{4}$ "
Iodine, pure	1 "

Let the collodion rest for a month or six weeks, when the red colour it possessed at first will have changed to yellow; and it will yield a very fine and tenacious film.

Bath of Nitrate of Silver.

Nitrate of silver, crystallized	26 grains
Water	1 ounce
Acetic acid	15 minims.

Let the plate remain at least a minute or two in the bath; wash in the ordinary way.

Tannin Solution.

Tannin	26 grammes
Distilled water	1 ounce
Alcohol	10 ounces.

Pour on as usual.

Development.

For negatives to be amplified make the following solutions:

No. 1.—Pyrogallie acid	1 grain
Water	5 drachms
Acetic acid	25 minims.
Alcohol	10 "
No. 2.—Gallic Acid to saturation.			
No. 3.—Nitrate of silver, crystallized	3 grains
Water	100 minims.
Acetic acid	5 "

Filter each solution. After exposure I take the plate, and, having previously varnished round the edges with a good varnish, I moisten the film with a little distilled water, without washing. I next pour upon the plate sufficient of solution No. 3 to cover it, and let it remain for at least a minute, during which time I mix in a graduated measure the following:—

Solution No. 1	80 minims
Do. No. 2	4 drachms.

In this I pour about twenty drops of acetate of ammonia. I stir the mixture, and, having poured off the solution with which it was covered, and drained well, I pour on this mixture. The image starts up at once. Keep the plate in motion until the solution becomes turbid, then pour it off, wash well, and then fix with hyposulphite, as sufficient vigour will have been obtained. If now the exposure is seen to have been too short, and all the details are not out, it is necessary to begin again, at all times having care to avoid too great intensity.

This method of developing has a great advantage in producing negatives for enlargement; the negatives can be very fully exposed without fear of producing the red colour given by pyrogallie acid alone, a colour which materially retards the production of prints by the solar camera.

PHOTOLITHOGRAPHY.

BY P. LISEGGANO.

An ingenious Viennese, M. Quaglio, has communicated to the Photographic Society of Vienna, a new process of photolithography, which gives superior results.

M. Quaglio employs *oleate of silver*, or silver soap, which he prepares by precipitating a solution of Marseilles soap by means of nitrate of silver. The silver soap is a yellowish white body, soft, like wax. It is rapidly decomposed under the influence of the sun: 5 to 7 minutes suffice to blacken it completely. It is possible that this substance may some day be much employed in photography; we can put it on metals, wood, ground glass, stone, &c. Exposed to light under a negative, it yields a proof of a fine glossy black colour. The proof is fixed with diluted hydrochloric acid, and afterwards with hyposulphite of soda or cyanide of potassium.

In creating his new process, M. Quaglio remembered the theory of lithography: upon a stone composed of carbonate of lime, he makes a design with the aid of black soap (oleate of soda); the stone is covered with diluted acid (either nitric or hydrochloric.) Decomposition takes place, the soda of the soap combines with the acid, and the oleic acid forms with the lime of the stone, oleate of lime, a fatty body, insoluble in water. In covering the stone with a solution of gum arabic, the latter penetrates the stone only in those places where there is no oleate of lime; if we moisten the stone, the parts where the gum arabic has penetrated will not receive the oily ink, which attaches itself only to the oleate of lime.

M. Quaglio covers the grained lithographic stone with a solution of gum arabic, and washes it with water after it has been several hours dry. The stone is then covered with the silver soap by means of a small tuft of flannel, it is then exposed under a negative in the sunshine for half an hour. The proof comes perfectly clear and fine. The stone is washed in rectified naphtha, gummed and blacked as ordinary lithographic stones are blackened, by dipping a sponge in gum, essence of turpentine and wax colour, which is passed over the design.

In the author's experiments, a portrait from nature, 3½ inches by 4, was reproduced on the stone in the manner described, and a proof taken with all the shades and half-tones. By blacking the design four or five times, and treating it as an ordinary lithographic stone, two hundred perfectly successful proofs were obtained.—*Le Moniteur de la Photographie*.

YELLOW VARNISH FOR THE WINDOWS OF AN OPERATING ROOM.

This varnish consists of a mixture of the following substances:—

Benzine	200 parts.
Orleans	40 "
Gamboge	40 "
Elemi Resin	1 part.
Dammar	1 "

The solid substances are pulverized and dissolved in the benzine. The filtered solution is poured upon the glass in the same manner as collodion.—*Le Moniteur de la Photographie*.

ON A NEW KIND OF MINIATURE, POSSESSING APPARENT SOLIDITY BY MEANS OF A COMBINATION OF PRISMS IN CONTACT THEREWITH.

BY HENRY SWAN.*

THE invention I have the honour of bringing under your notice this day is new, and the effect very beautiful, but it is neither for its novelty nor for its beauty that I would chiefly claim attention, but because in its application to miniature portraiture we find we have the means of adding greatly to our power of defining form and expression. So much so that it is by no means unusual for me to find that the same photographic plates which give an unsatisfactory likeness when printed as an ordinary

flat portrait, will, when printed and used for this kind of portrait, render the expression so much more perfectly, that the likeness is at once far more pleasing and far more truthful. Indeed, a careful comparison of a considerable number of the same pictures shown both as flat portraits and as portraits in relief will soon satisfy the artist that there are many niceties of form and expression which flat portraiture is wholly inadequate to render. But I trust that if the specimens I shall now place before you be not sufficient to show you that we have here great additional power of expression placed at our command, it is only because you have not here the same means of forming an opinion that you would have had these been portraits of your own personal friends. The novelty will wear off, and the eye will become accustomed to their beauty, but the power of giving more of the truth, more of the living soul to the likeness of one's friend, will remain, and remain to be felt the more, the more we become familiar with these vision-like images.

As to the means by which we are enabled to catch these Lilliputian "doubles," and imbed them apparently in the crystal as flies in amber; those among you who are conversant with the phenomena of binocular vision will, no doubt, have already guessed that each portrait is compounded of two pictures, and is in itself a stereoscopic apparatus. And such, indeed, is the case. The catching of the images is done by the ordinary modes of obtaining transparent pictures on glass; the union and combination of the two flat pictures so as to produce the true stereoscopic image, I manage by taking two rectangular prisms of flint glass, or crystal ground to an angle of about 39° or 40°. These two prisms I place together, with their widest sides in contact, or nearly so, so as to form one solid quadrangular prism, divided lengthwise by a thin film of air. Now if I stick a blue wafer on one side of this combination, and a red one at the back, I shall find that, when I look straight at this combination, the rays which reach one of my eyes are those which are transmitted directly through the prisms, so that with this eye I see the object which lies at the back. On the contrary, the rays which reach the other eye are not from the back, but from the side only, as they are reflected from the surfaces of the prisms where they touch either. Hence with this eye we see by reflection the object at the side, which, however, appears to be at the back, like the other. Thus, if I stick the red wafer at the back and the blue one at the side of this combination, with my left eye I shall see the red wafer, with my right eye the blue one, which will occupy precisely the same position. If now I look with both eyes I shall see apparently but one wafer, and that of a purple hue, this being the result of the red and blue images being superposed on each other.

In fact, if we draw a line perpendicular to the surface of the prism next the eye, all the rays which fall on one side of that line will suffer total reflection from the inner oblique surface of this prism, while nearly all the rays which fall on the other side of this line will be transmitted direct through the two prisms.

If now we substitute for the red and blue wafers the two slightly dissimilar pictures which constitute the stereoscopic pair, we, of course, obtain the image apparently solid. It, however, requires some experience and skill in mounting the transparent pictures, as, if they are not set rightly, they may distress the eye, which should have the same feeling of ease as though the image were of carved ivory.

In thus bringing before you an invention which carries the art of miniature portraiture a step further than has hitherto been done, I should like to conclude my description of the simple means by which this has been attained by a few words on what we may expect to get from this branch of human art—remarks which are not the less needed now that this kind of representation, in the form of the carte de visite, has become almost obtrusive at our social gatherings.

I know there are some who consider that it is mainly to vanity and egotism that we may attribute the wide-spread popularity to which these have now attained. To my mind vanity and egotism quite as often get from them a wholesome rebuke. It is rare for a first portrait to please. It falls far below the sort of ideal we have set up in our own minds as to the appearance we present to the gaze of the unthinking multitude.

There are, however, other phases of feeling which have a much larger share in the delight we experience in turning over these sun-stained tablets. Right on the surface lies natural affection, giving an interest and meaning to faces and forms, that to us, who know not the originals—have never laughed,

* Read in Section A, British Association, at Newcastle, on Tuesday, September 1st.

played, sung, danced, or wept with them—may seem but a little better than those displays of elegance we meet with in the windows of the enterprising milliners and tailors.

Then, again, men, yes, and women too, experience a glad sense of relief at their escape from the silly, stock-flatteries of the second and third-rate miniature painters. I do not say this in undue disparagement of these men. They painted for their living. They gave what best insured that living, and it is great cause of thankfulness photographers have not the same power of modifying their productions to meet the requirements, real or fancied, of their subjects. The ordinary photographer is mostly limited in his efforts to the trying, as far as his means will permit, to show how much the form and figure of his sitter would adorn princely halls, had it pleased Providence to place him in such a station, efforts which too often are not sufficiently seconded by his uneasy subject. However this may be, it is certain that we do feel that there is and must be a considerable amount of genuineness about a photographic portrait. We know that if it does not exactly fulfil our ideal of the man, yet that at the time he was taken, he must have looked very much after that fashion, and, at the worst, it is some satisfaction to find that there is so much in common between us and this and the other great man, that it is perfectly possible for him to look sulky or foolish under the same circumstances that makes us look the same. In further proof of this genuineness you will find it often not a little amusing, as well as instructive, to compare a portrait which has filtered through two minds, the painter's and the engraver's, into mere vapidity, with that which comes from the emotionless glass, recording every unconscious grace or conscious awkwardness.

There is yet another meaning which may be read from the gilded pages of a lady's portrait album. If only we had the cypher, so that the writing were more easily legible, here lies the most truthful records of life yet possible for us. We may look on many a human habitation, and be able to make but a very faint guess at the history of its inmate. It is not so with these

fleshy habitations. They are built up by the spirit within. The pen of the recording angel is no fiction; even here on earth, every living spirit fulfils that office and every varying play of light and shade tells its tale of the human soul within. Ay, and as in a Gothic cathedral, we trace one part as the work of an age of rude force, another of skilled mastery, or the gentle cunning of a sensitive soul and laud, and perhaps another of dull ostentation and empty pride; so in every truthful portrait we may see plainly or dimly, according to the perception God has given us, how this man has been builded up. How, perhaps, at some time or another, he has had frank, outspoken freedom for ancestors, and has inherited the same nature, a nature that both will not, and cannot live, except in freedom. Another is a born vassal, and seems a valet in his master's clothes. Some show cruel, wolfish eyes, while others have the gentle lustre of the deer. There, too, is to be seen, plainly or dimly, according to the perception God hath bestowed, what the living man himself has built upon the foundations of the dead. Here is a front worn with toil, and scarred with fight, yet peace beneath. There, a desecrated ruin; so desecrated, so ruinous, that we can hardly trace that there is enough of the living spirit left to hold the whited sepulchre from crumbling to pieces.

Look on these portraits, and, if you have insight, you may give more than a guess at what the man *is*, though you may know little or nothing of the steps by which he came to his heights or depths. Thus, when you have your likeness taken you are having your history written, perhaps as fully as it ever will be. Every turn of the lip, every bend of the brow, the very hang of the fingers, tells its tale, saying, "In some past times, such and such influences have been at work to mould this man, and *now* we see how far they have been permitted to leave their stamp, the inward being, sooner or later, moulding the outward image, and its light ever shining more and more clearly through.

EDÉN'S MICROSCOPIC CAMERA.

SOME months ago we noticed an ingenious camera, invented by Mr. Edén, for producing either enlarged images of microscopic objects, or microscopic photographs of large objects. We learn that this instrument, which was patented, is manufactured by Mr. Howe, successor to Knight, of Foster Lane. We subjoin a diagram of the camera, together with Mr. Howe's description.

"The instrument described below has been invented for the purpose of taking magnified microscopic objects, minute photographs, commonly called micro-photographs, and miniature photographs from life, for rings, small lockets, &c. I will first describe the plan of taking magnified microscopic objects. The object to be taken, which is generally mounted on a slip of glass, 3×1 , is placed in the small camera box marked A in the general plan, and which box is fully drawn and marked B. There are four brass pins on which the mounted object to be taken is placed, and there are six longer pins which go round the edges of the glass plate and keep it in its place. These pins go through the small mahogany box, and are fastened into a brass plate which slides into dovetails, and can be taken in and out at pleasure. Attached to the small mahogany box is a brass lid lined with mahogany, and to which two silver springs

are fixed. This lid shuts down on the object, and is fastened by a small brass hook. On the top of the lid a piece of tube is screwed, into which slides another tube containing two lenses, and which act as a condenser to condense the light reflected from the mirror C. There is a lens inside the tube, at the end of which the box (A) is fixed, and this lens is adjusted by means of the milled head E. It shows a magnified image of the object on the ground glass at the end of the large camera. When the sensitized plate is ready, you remove the ground glass and substitute the sensitive plate in the usual manner. About two minutes' exposure will be required if the sunlight is reflected from the mirror, and ten minutes if an ordinary paraffin lamp is used. The mirror is adjusted by sliding it on the tube F. The pictures are printed from the negative in the usual manner. I will now proceed to describe the method of using the instrument for taking micro-photographs. These are taken from a negative which is fixed in a frame at the large end of the camera. The mirror C is removed from the small end of the camera by sliding it off the tube F. There is a large flat mirror at the large end of the camera fitted in a frame and marked G, and which is adjusted to any angle for the purpose of throwing the light on the negative, and when adjusted is clamped in its place, by means of the small

clamping screw H; you must now place a slip of glass, 3 x 1 inch, scratched with emery paper, the scratched side downwards, on the four pins previously described, and slide the condensing lens so as to get a sharp image of the scratches on the glass. Adjust the object glass by means of the milled head E, and while looking through the condensing lens (or, as it is used now, a focussing glass) make the image of the negative which is at the other end of the camera coincide with the scratches on the glass. Now remove the small camera from the dovetails, and take it in the dark chamber, close the shutter, and take the focussing glass out and put in its place a bit of cork. Remove the slip of glass with the scratches on, and substitute another with a small drop of collodion, prepared in the bath, and replace the box in the dovetails; expose for about ten seconds, and develop and fix in the usual manner. The way to take small full-length pictures from life is to unclamp the sliding bar, when the flat mirror can be removed. Take the negative out, and place the sitter opposite the large end of the camera. You then manipulate in the same manner as for the small micro-photographs."

PROCESS FOR PRINTING POSITIVES WITHOUT THE SALTS OF GOLD AND SILVER, AND FIXING IN PURE WATER WITHOUT HYPOSULPHITE OF SODA.

BY M. DE MOTILEFF.

I HAVE presented to the Photographic Society three kinds of positives taken without the salts of silver or gold: their colours are *blue*, *deep green*, and *intense ink-black*.

Before describing my peculiar processes, I must declare that they are based upon chemical reactions, known for a long time in chemistry, but which I have for the first time applied to photography; they are also results sought and studied for a very long period of time. Most of the photochemical reactions for obtaining positives without the salts of silver and gold, which were indicated by MM. Poitevin, Niece de Saint Victor, Schnauss, Hardwich, and others, I have experimented upon, and rejected as being too complicated and uncertain, or as affording too little sensibility to light, or, finally, as producing results which have no artistic value.

The idea pursued by me in my researches was to obtain the desired colour directly, by the action of light, preserving the whites perfect. I solved this problem affirmatively for blue and deep green colours; as to the black colour, up to the present time I obtain it by toning, but I hope to obtain it by the direct action of light.

Blue and Deep Green Colours.

I make use of chemical combinations completely different from those hitherto recommended; the paper is floated in the bath during five minutes. After becoming quite dry, it is exposed under a negative during a period of time varying from thirty to fifty minutes, according to the intensity of the negative, under the influence of the solar rays, the picture is produced of a blue or deep green colour, without the aid of a toning bath, which is indispensable in other processes; withdrawn from the toning bath, the proof is washed in ordinary water, and the operations are finished.

Considering the artistic value of the proofs, the simplicity of the manipulations, and the economy of the process, I believe it will prove useful for views, seascapes, for taking positives while travelling, but especially for wood engraving.

Up to the present time, we know of no method of photography on wood without a medium; this has always been a film interposed between the picture and the wood, either albumen, collodion, or other coating. This coating always obstructs the engraver, and by scaling under the tool renders the cutting almost impossible, while by my process we may

obtain very definite photographs on wood, without the aid of any coating, and even without altering the wood.

My materials applied to the surface of a lithographic stone, yield a perfect design; I am now occupied in seeking the means of rendering this design capable of receiving lithographic ink.

Photographs in very Intense Ink-Black.

The paper is placed on the bath during five minutes and dried, then exposed to the sun under a negative from twenty-five to fifty minutes, it is then withdrawn from the pressure frame, well washed in ordinary water and passed through a bath which transforms the picture into sesqui-oxide of iron; after washing in ordinary water, the proof is passed into a toning bath of gallic acid and other substances. This toning bath yields a very intense ink-black. I must add in this place, without wishing to boast of my process, that among the processes hitherto published for obtaining positives with gallate of iron, mine gives the best results. Having during the past year visited Dr. Schnauss, at Jena, I had an opportunity of seeing the results he had obtained by means of gallate of iron. I have also studied the other processes, and I can declare that my process is the only one which gives intense black, while preserving the whites in a satisfactory state.

The improvement that I am now seeking for my process is to increase the sensibility. In its present state the printing is nearly two and a half times slower than with chloride of silver, but we must also take into consideration that the washing after fixing is dispensed with. At the present time I am making experiments upon albumenized paper.

As to economy, a drachm of the sensitizing bath (20 per cent.) costs about a penny, the toning bath less, the stability of the proofs is not so great as that of carbon prints, but greater than that of proofs in chloride of silver; besides, that is a question of time. I have remarked that with time the blacks, instead of becoming weaker, grow more intense; the cause of which is, I think, the oxidation of the iron.

In the course of my photochemical experiments, I composed a bath which contained only of 1 part of nitrate of silver to 100 part of water, and with albumenized paper it gave very remarkable results.—*Le Moniteur de la Photographie.*

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, September 2nd, 1863.

It may perhaps be remembered that M. Dornbach, a young artist photographer, of America, met his death by the explosion of some gun-cotton he was packing in a cask, making use of a stick to force it down. It is questioned whether the explosion was caused by electricity or by friction, but the high temperature required to inflame gun-cotton may lead us to doubt whether the friction of the stick against the sides of the cask would evolve sufficient heat, although we cannot undertake to say it would be impossible. Dry gun-cotton is a highly electrical substance, developing a great quantity of resinous electricity by friction, and it is highly probable that in the operation which cost M. Dornbach his life an electrical spark inflamed the mass. Such is the opinion expressed by Dr. Phipson in the *Moniteur de la Photographie*, who has also the following observations on the development of free iodine in collodion:—

"Those who have read the papers of Mr. Hardwich, referring to the development of free iodine in collodion, will remember that he attributes it to the presence of ozone, or of the ozonized principle in ether, and it is true that in certain circumstances ether, like essence of turpentine, can engender allotropic oxygen. But hyponitric acid, N O₂, which exists in dissolved pyroxyline, acts exactly like ozone, and it will be difficult to prove the existence of the latter in presence of the former."

We know that pyroxyline is decomposed by the alkalis; we know also that iodide of potassium has an alkaline reaction, and that the iodide of ammonium is very easily decomposed. It is therefore, in my opinion, by the reaction of the alkaline iodides upon the pyroxyline of the collodion that free iodine is developed in that liquid, and not by the ozonization of the ether which has been exposed to air and light, as Mr. Hardwich has it. Light appears to favour this decomposition. The proof of what I advance is that the non-alkaline iodides, such as the iodide of cadmium, do not act upon the pyroxyline, and the collodion prepared with these latter usually remain colourless.

Messrs. Millon and Cornaille recommend for precipitating old silver baths the addition of proto-chloride of copper dissolved in ammonia. In this case, as every chemist knows, pure silver is precipitated, as when we make use of sulphate of iron.

Mr. Emerson Reynolds recommends for the preparation of this product the dissolving the black oxide of copper in hydrochloric acid, and, when it is all dissolved, to add ammonia, which produces a pale blue solution.

Upon this, Dr. Monckhoven remarks, in the *Bulletin Belge*, that he regrets to say the preparation indicated by Mr. Reynolds is practically very difficult. First, we must commence by procuring the black oxide of copper (employed for combustion in organic analyses), and then the operation does not always succeed. It is infinitely preferable to employ copper turnings, or very fine copper wire, boiled for half an hour in commercial hydrochloric acid, then throwing the whole into a large glass vase containing cold water. A white crystalline powder is precipitated, which is speedily collected in a bottle and ammonia added to it.

But let us say at once that the method indicated by MM. Millon and Cornaille is very inferior to that which consists in placing a plate of copper in the old silver baths. In the course of a few hours the silver is reduced. We can also employ a solution of sulphate of iron which is poured into the silver bath: all the silver is precipitated as if we had made use of ammoniacal protochloride of copper, only we are obliged to melt the metal, for it always contains bibasic sulphate of iron, which is separated by fusion.

M. Lacan makes the following communication to the readers of the *Moniteur de la Photographie*.

"We have had communicated to us a fact, the importance of which our readers will fully appreciate. About a year ago, M. Wothly announced that he was in possession of a new process of printing positives on paper without iodide or chloride of silver. Since that time M. Wothly has pursued his researches, and now his discovery is complete. The inventor has shown us a great number of specimens which leave no doubt as to the excellence of his method; many of the leading Parisian photographers who have also seen them are struck with the superiority presented by these pictures over those obtained by ordinary means. The proofs M. Wothly gave us to examine, and which are of all dimensions, from *cartes de visite* to enlarged portraits, resemble in aspect those produced upon enamelled paper. They are remarkable for limpidity and transparency. The whites are extremely pure, the half-tones of remarkable delicacy, and the shades very vigorous. Upon comparing them with positives upon chlorided paper taken from the same negatives, we cannot but perceive that they are infinitely preferable.

"The basis of the operation by which these pictures are produced are entirely new. As the silver salts are replaced by others much cheaper, an economy of 70 to 80 per cent, is obtained. While the time is abridged in the proportion of 1 to 4, the sensibility of the paper is four times greater, and the proofs offer every guarantee of permanence, hyposulphite of soda is not employed for fixing. Lastly, the method is as easily practised as those now employed, there being very little difference in the manipulations.

Upon this Dr. Van Monckhoven remarks—"As our friend M. Lacan calls the attention of his readers to M. Wothly's invention, and as it will be his duty to reply to all the ques-

tions which will be addressed to him on the subject, we put to him, *in the name of all his readers*, the following, — Do you wish to make known Mr. Wothly's process? Now that we have allowed the *Moniteur de la Photographie* to speak, we shall say to our readers that M. Wothly's pictures, which are now before us, greatly resemble those obtained by ordinary processes, but their violet hue is not so rich.

"We have undertaken a series of experiments to penetrate the secret of M. Wothly's process, and say, at once, that these proofs are obtained from silver and protoxide of iron. There is not, says our friend Lacan, in M. Wothly's proofs, either iodide or chloride of silver. We believe so; but if he says to us *non bromide*, we shall doubt it.

"In brief, we certainly consider the discovery made by M. Wothly as very interesting, but we wish to hear no more upon the subject, because our readers will derive no benefit from it. I appeal to my friend Dr. Schnauss, that he will make known through the journals his experiments on the proofs in question. I, on my part, will publish mine in the pages of the *Bulletin Belge*."

PHOTOGRAPHY IN CAPE TOWN.

SIR,—As a subscriber and constant reader of the *News* since it started, allow me to address a few lines to you, and, if I scramble on in an uninteresting way, pray put the missive into your rubbish basket. I have long intended to send you some views worthy of your acceptance, but years have crept by, and I will not wait longer. Twelve years ago I commenced with Talbot's process, but the collodion soon upset that for portraiture, and I have ever since been a steady follower of Archer. I frequently meet and hear of wonderful cases of the art being acquired in the short space of a few mouths or so, but I have been at it many years, and I honestly confess there is much to learn.

I hear and read a good deal about hot climates being unfavourable for the constant practice of photography, but, although it is undoubtedly unpleasant to work in a very high temperature, I do not see any material difference between South African and European productions. The greatest nuisance here is the difficulty of obtaining good albumenized paper—it is so variable in its quality. Mr. Matheson, in one of your recent numbers, gives a drawing of a glass house he suggests for hot climates, and accompanies it with some very excellent remarks, but I think a far better arrangement is that proposed by Mr. Sutton. I am now working in the fourth studio I have had in this colony; it is built on Sutton's plan, with the dimensions slightly altered. The side lights are twelve feet high by eight feet wide, the front light twelve feet wide by two feet high. The only objection I find is a deficiency of front light, and I am just having the alteration made suggested by your *News* of the 6th of March, fig. 2, to slope the sash from *b* to *d*, making it three feet wide. The house is built of brick, and is very cool compared to the old plan. The last house I had here was frightfully hot in the summer. In the summer of 1861 the thermometer stood at 105° at 9 o'clock A.M. The highest temperature, at any time of the day, in my present one, was 90°. I cannot conceive how Mr. Rejlander can obtain sufficient light in his new studio, though I readily admit that more failures arise from the excess than from a deficiency of light. Tissue paper on the glass softens the light very much. The suggestion made in the *News* to varnish it would, I think, make the light too strong for this climate.

I wish the manufacturers of apparatus would improve the dark slides they make for professional photographers. They should be stronger in every part, and an inclined groove, with sponge at the bottom, would ensure cleanliness and preserve the slide. The rolling presses would be much improved by having the steel plate with a thin layer of silver. Would it increase the expense materially?

In your article on "Silica," you observe that water extracts from glass potash and soda; may not this explain the

deterioration of some of our silver baths? I intended sending you a drawing of an instantaneous shutter I made about two years ago, but I do not suppose it would be worth while; I have not seen any that work exactly like it. It opened from the centre, and, for compound lenses, I did not find it answer; Dallmeyer's principle I prefer. We have not many amateurs here, but foremost among them is the Rev. Mr. Curtis; he is an ardent lover of the art. He has kindly given me a few of his stereographs to forward to you.—I remain, yours very obediently,

ARTHUR GREEN.

Cape Town, July 20, 1863.

[The stereographs enclosed are excellent specimens of photography, and very interesting. We shall have much pleasure in receiving the further letters promised from our correspondent.—Ed.]

PHOTOGRAPHS IN PRINTING INK.

STR.—Some time ago I sent Mr. Pouncy a few impressions of carbon prints on sheet gelatine, with a suggestion that the substance, from its transparency, would likely be useful for the production of transparent positives to be converted again into negatives, as the slowness of printing by this process will be much against its usefulness. He stated, in reply, that there was an objection to its use on account "of its tendency to move under the negative according to the temperature." However, in my experience, I have not found this to be the fact. The facility of making this substance, its even texture and transparency, combined with cheapness, induced me to give it a trial.

Sheet gelatine is manufactured in sheets of various sizes and shades of colour, and is now extensively used in the arts. Its manufacture being a trade secret, little is known about it, or how the beautiful surface is produced on the French prints which are exhibited in the stationers' windows. I have applied it with considerable effect in glazing photographs, &c., &c.

I, therefore, through the pages of the PHOTOGRAPHIC NEWS, give publicity to the manner in which sheets of gelatine can be made as well as the gloss on the surface of a photographic or any other print can be produced, with an important improvement of my own, giving, in addition to the gloss, a collodion surface perfectly waterproof, as well as the means of effectually securing on plate paper the transferred carbon print.

Procure a sheet of plate glass of any convenient size, or any number of them if you wish to do business extensively. Have them placed upon wooden racks, on supports, so that their surface be perfectly level when at rest, and out of the way of dust. Carefully clean them in the usual way for photography. Get from the butcher some ox gall, into which dip a piece of flannel or cloth and smear the top surface of the sheet of glass carefully and evenly and allow it to dry, passing on to the others. When all are dry, prepare some gelatine of the clearest description, having previously boiled in an earthenware vessel in which a small piece of alum has been introduced. Pour this gelatine solution from a small jug or bottle into the middle of each plate of glass, and be careful that it covers it all without overflowing the edges. In a few hours the gelatine will have set, and at this time it is that a damp print or photograph may be applied, face down upon the gelatine surface, taking care no air bubbles are introduced; if any press them out by turning over the glass and examining it. In two or three days the gelatine, and with it the print, will have dried, and when perfectly so, an incision is made with a penknife round the edges of the print. Lift one corner, when it will be found to rise, carrying with it the gelatine, retaining the gloss of the glass from which it has parted.

Dyes are introduced into the gelatine in its fluid state to impart the various shades of colour, and by allowing the gelatine to dry upon the glass, without covering it with

prints, &c., &c.; you can have sheets as large as the glass on which it is made. The improvement I have made for waterproofing the surface is the coating the glass plate with plain collodion thinned down instead of ox gall. The covering of its surface with the sensitive photographic ink previous to cutting the gelatine from the glass plate enables you to have a clean and even surface, and the transparency of the substance enables you to expose from the back, thereby effectually securing the half-tone; and if the gelatine be thin, you will have a finer detail than it is possible to obtain by any other means.

These prints, as well as those on paper, can be transferred to sized plate paper by following the directions here given:—

Damp the plate paper with a solution of strong clean gelatine; place the carbon print between damp blot sheets; have a lithographic press with clean stone on the carriage; lay the back of the print upon the stone, and the plate paper over it, gelatine face down, on the carbon print; pass all through press once or twice; take the pressed sheet out and allow it to dry, when it will be found that the gelatine on the plate paper holds all, the carbon print parting with its former surface, whether of sheet gelatine or paper.

In a future number I may have some further remarks to make on the subject.—I remain, yours respectfully,

FRANCIS S. BEATTY.

Photographic Notes and Queries.

LIQUID COLOURS FOR PHOTOGRAPHS.

STR.—A short time since, fluid colours for colouring photographic portraits were introduced to the notice of photographers, and I was induced to invest in a set, and on using them was much pleased with the quick and easy mode by which card portraits could be touched off, and in all the glories of bright crimson, blue, scarlet, and many coloured table covers, curtains, carpets, &c., &c., handed over to my patrons without the delay of the good old fashioned plan of water or oil colours. Of course a few were highly finished and placed in the window, and there in a few days every trace of colour vanished, leaving the photograph in no way improved by the "top dressing." My old colour box is again in its place, and I shall be rather more careful in my next experiment of saving time and trouble, when colouring photographs. Really, Mr. Editor, I think that dealers should be a little more careful in introducing these sort of things without testing them, as anything of this sort is likely to destroy faith, and cause unpleasantness between the photographer and his visitors.—Yours truly,

THOS. GULLIVER.

18, Union St., Swansea.

[So far as we have seen hitherto, most of the liquid colours applied to photographs have looked vulgar. Those we described a few months ago, for giving a general tint to the paper, are not fugitive: the specimens we tried retaining their colour perfectly.—Ed.]

PHOTOGRAPHIC DISCOVERIES.

STR.—I noticed the papers of Mr. Lewis in your two last numbers, but really I cannot see anything new in his transfer process first described. Is it any other than from Mr. Pouncy's last patent process? Are not the ingredients Mr. Lewis uses the same, only he manipulates somewhat differently? You will, doubtless, remember that in Mr. Pouncy's specification he speaks of his process as of peculiar advantage for transfers. There is no doubt but the process will become of great service in different branches of photography, but I think it is only right that parties making use of it in any way, should acknowledge to whom they are indebted, and not come before the world with something *new* of their own, when, in reality, it is not theirs, but borrowed.

Mr. Lewis is, perhaps, not aware that we are very jealous for the honour and rights of our countryman, whose name, in connection with photography, will, doubtless, last, and deservedly, as long as the art itself.—I remain, Sir, your obedient servant,

DORSET.

[We are also very jealous of seeing any inventor robbed of any share of the honour due to him, and award all praise to Mr. Pouncy for his skill, perseverance, and success. But our correspondent is in error, we think, in his deductions. The process described by Mr. Lewis is essentially different in method from that of Mr. Pouncy. We know Mr. Lewis to be an old experimentalist and a highly intelligent man, and see no reason whatever to doubt that the process is due to his own observation and experiments. Our correspondent probably forgets that the same materials of printer's ink or transfer ink, mixed with bichromate, have been used in photolithography before Mr. Pouncy had patented his process. Mr. Gibbon used copal varnish and linseed oil, mixed with bichromate, as described by Mr. McTear, eight months ago, at the Glasgow Society. Some have objected that this fact would vitiate Mr. Pouncy's patent. But we regard it as neither vitiating his patent, nor detracting from his merit, which consists, not in discovering new sensitive agencies, but in a clever adaptation and application of those already known.—ED.]

Talk in the Studio.

SENSITIVE PLATES FOR THE MARSEILLES COMPETITION.—M. Vidal, secretary to the Photographic Society at Marseilles, informs us that sensitive dry plates may pass the custom house without exposure to light, if certain precautions are taken. It is necessary that both the package and the declaration distinctly state that the parcel is in transit international, and that it contains sensitive photographic plates, which will be spoiled if they are exposed to daylight. We may here mention that the paragraphs in French and Italian given in our last contain one or two orthographic blunders, which escaped attention in the hurry of going to press. In line 8, for "aneun" read "aucun;" in line 12, for "osseroare" read "osserare;" and, in line 14, for "aggetti" read "oggetti." We should also remark that Mr. Cole uses two thicknesses of glass—one yellow and one green, to ensure protection.

To Correspondents.

- J. PENRICE.**—We regret to state that No. 198 is quite out of print. We may possibly be able at some time to procure a copy for you; but it is uncertain.
- H. P.**—On adding carbonate of soda to a bath containing acetic acid you form acetate of silver in the bath. Some portion of this will be reduced by long exposure to sunshine, and may then be filtered out; but it is difficult to get entirely rid of acetic acid when it is once added to a nitrate bath. 2. A good double combination is most suitable for instantaneous street views. 3. For groups a good portrait lens, or the triple. 4. For interiors a portrait lens, or the triple. 5. We have seen some good results produced by the lens you name. We did not see you or hear of your call at our office. Stamps value one shilling received for the case of necessity.
- B. W. B.**—It is not necessary to have any light on the camera. On the contrary, the more completely it is in shadow the better. All the light should be on the sitter. If your pictures are too dark it is from too short exposure or insensitiveness in your chemicals. A very weak bath would operate against sensitiveness and vigour.
- H. N.**—The brown patches arise from imperfect fixation, probably from the prints sticking together in the hypo, which may also possibly have been old or weak. The insoluble hyposulphite of silver has thus been formed which decomposes whilst the print is washing or on exposure to light and air, causing those dirty yellow or brown stains.
- G. G.**—It is probable from your description that your bath has been made of adulterated gutta-percha. When this is the case the bath may sometimes work well for years, and then begin to act injuriously from a slow process of decomposition having set in. 2. We have no personal knowledge of the practices of any of the houses you name. We know No. 1 personally, and deem him a respectable man.
- N.** We should attribute your trouble primarily to the collodion, or, rather, to the pyroxyline of which it was made. A change in the sample of collodion would be the first remedy to try. A less acid bath; perfectly clean and dry plates; and more perfect setting before immersion would aid in preventing the trouble. Your suggestion as to uneven drying causing the film to split is very likely correct; but, without the tendency in the collodion, it would not be sufficient to produce the result. Treating the plate with dilute gum water, or dilute albumen, before it dries is often found a remedy when the tendency exists.
- THOMAS R. BANKS.**—The formula you quote contains double the proper quantity of acetate of soda. The proper proportion is 30 grains to each grain of chloride of gold. Too much would cause slow toning.
- HISTORY.**—We do not clearly understand the class of papers to which you wish to refer. Historical allusions and accounts of the origin of different processes are to be found profusely scattered through our pages; but a consecutive history of photography remains to be written. You will probably best obtain what you require by searching through the indexes to the volumes of the PHOTOGRAPHIC NEWS. 2. The best proportion of double sulphate of iron and ammonia depends upon a variety of circumstances, such as the kind of collodion, light, subject, &c. We have known sufficient intensity produced at once when using it of various strengths, from 12 grains to 120 grains in an ounce of water.
- S. J. L.**—A variety of preparations have been used as substitutes for ground glass in mounting transparencies. One of the best is a "crystal" varnish or amber varnish, with a little white wax. Spirit varnish applied cold may be used, or thin starch.
- P. J.**—Make a solution of iodine in alcohol, about 10 grains to an ounce. With this rub the silver stain well, and then apply cyanide of potassium, and subsequently rinse with water.
- H. P.**—If prints discolour on bringing to the light after they have been in the hypo bath, it is from imperfect fixation. None of the prints you have forwarded appear, however, to suffer from that cause. Their defects arise from various causes. Primarily imperfect negatives, a tendency to hardness, with abundance of spots, prevailing. Some of the defects arise from under-printing; some from over-rapid toning, probably with a newly-mixed bath; and some from imperfections in the paper, the albumen having run in streaks and waves. As the prints are not numbered for reference, we cannot point out individually the evils in each.
- JOHN DAVIDSON.**—We do not know anything of the gentleman you name; but will make some inquiry.
- W. W. S.**—The deposit on the shadows, readily rubbing off, caused when using a newly-mixed iron developing solution, arises from too much reducing energy. The addition of more acetic acid, or of some old developing solution will prevent it. Keeping the developing solution a few days will also prevent it.
- J. B.**—The method of intensifying to which you refer is frequently very useful, and we have used it for some purposes for many years. The instantaneous pictures of Colonel Stuart Wortley were chiefly intensified by such a method, as you will see on reference to his paper in the PHOTOGRAPHIC NEWS, February 13th, 1863.
- CASTLEBERG.**—We have no knowledge whatever of the ability of the gentleman to whom you refer. He may, or may not, be very capable so far as we know. If you send us an address and stamped envelope we will send you the address of a gentleman we know.
- J. POUNCY.**—A few remarks on the subject in our next.
- J. H. G. 42.**—Mr. Bertsch's automatic camera is a clever little contrivance, with an ordinary single lens of so short a focus that all objects beyond a few feet distant are always in focus. You must generally receive the statements of inventors *cum grano salis*. The images, when enlarged to the extent described, show both distortion and loss of definition.
- DOUBLE X.**—Mr. Parkinson uses bromo-iodized collodion and iron development, as described in our last ALMANAC. Besides keeping his chemicals in good condition he has an excellent light, and attributes much of his rapidity, in a letter just received, to the use of Dallmeyer's No. 2 B lens. You will not gain in rapidity by the use of saccharo-sulphate of iron, but will probably gain a little in intensity.
- J. BURNS.**—If your prints turn yellow from under-fixation the appearance will be dirty and mottled. If they turn yellow from the liberation of sulphur they will appear at first of a very delicate yellow. This may arise from the use of an acid fixing bath, or from the toning bath being acid, and the print going into the hypo without rinsing. We shall be able to give you a much better opinion on seeing one of the results.
- T. C. F.**—For architectural work, especially if the camera have to be brought near to the building, a triple lens. For groups a good portrait lens is best and quickest; but to get satisfactory definition and rapidity you must have a good lens. Blue will be a better colour than white for the interior of your studio. The latter is glaring and causes too many reflections. Thin, light blue blinds may be used instead of white. The amount of glass you can dispense with entirely depends on the position and nature of the light. We should prefer to cut off what was necessary with blinds which could be removed in dark weather.
- X. X.**—The triple is the most suitable lens for interiors, giving absolutely straight lines. We fear that you scarcely understand the requirements of the work you are engaged upon. Convergence of the perpendiculars does not depend on the lens, but arises from tilting the camera. If this be necessary to get in the upper portions, you must employ at the same time a swing back.
- T. G.**—You will find it much better to put your sitters to face the east and have the side light from the north.
- C. COLLIS.**—The question of want of actinism during the hot weather is a curious and interesting one. We do not think that the putting the plates into the bath immediately or letting the film set well had much to do with the result. Neither has the presence of alcohol in the developer, its sole office being to make the solution flow well.
- SEA SIDE.**—No. 2 on your list we prefer. It is very rapid, gives exquisite definition, and freedom from distortion.
- Several Correspondents in our next.

CHLORIDE OF LIME AND ACETATE OF SODA IN THE TONING BATH.

THE use of chloride of lime in the gold toning bath seems to result in very great success or very great failure. Experimentalists are either charmed with its results and enthusiastic in its praise, or disgusted with it and altogether sceptical as to its value. When recently we recalled attention to it and gave some verified formula, it was simply to meet certain inquiries, and instruct those who wished to obtain in portraiture fine black tones. The discussion of the subject has, however, created an immense amount of interest, and we have been inundated with letters seeking for information or detailing results. Some photographers have signally failed to obtain anything satisfactory, bleaching and mealiness alone resulting. The majority of the letters have, however, been enthusiastic in praising the results obtained.

Mr. Parkinson, of Dieppe, whose tones pleased us so highly a couple of months ago, has just sent us a batch of specimens, which, as rich, pure blacks, are superb. He has also sent us a long account of his toning experiments from which we shall make one or two extracts. The first mentioned formula, in which acetate of soda is used, as well as the salts of lime, is described as giving the best results with the least trouble and risk of failure; the prints to which we have just referred having been toned by it. Mr. Parkinson says:—

The acetate of soda and lime has proved most successful with me, and annexed I beg to hand you the formula I have found most successful; it will, I hope, help to put an end to mealiness. At the same time I beg to forward you other formulae that I have used with good success.

Into a bottle put the following:—

Chloride of lime	3 grammes
Acetate of soda	8 "
Carbonate of lime	8 "
Distilled water	100 "

Take 5 grammes of this solution and add to 1 litre of common water, shaking well, and then add a quarter of a gramme of chloride of gold. This is made up in the morning and generally used six or seven hours afterwards; it may be kept longer, but this is about the time we generally use it. The paper is floated for five minutes on 80 grains solution of nitrate of silver, slightly acid with acetic acid. The prints are slightly over-printed, well washed in several waters, and fixed in a nearly saturated solution of hyposulphite of soda.

The prints are put into the toning bath all together, and we find that one litre will tone from 120 to 150 cartes de visite, and will take about an hour to complete the whole. With this bath nearly any shade may be obtained, according to the length of time the prints are left in it. This is exactly as we use it, and I have tried it with several papers with the same success.

Annexed I beg to hand you other formulae I have used, but the first enumerated is my "Eureka" and my "Excelsior," and I am convinced that I shall be helping those in need if they only use it with a little judgment and patience.

From some of the formulae that follow, it appears Mr.

Parkinson has tried mixtures of almost all other toning baths, but as they tend rather to complexity than simplicity, it is, perhaps, not desirable to enter into detail, seeing that the results do not surpass, or perhaps equal, those of the more simple formula already given. One bath is similar to the formula published by Le Gray some years ago, and contains one grain each of chloride of gold, chloride of lime, and chloride of sodium, in five ounces of water. Some others follow, but with the reiterated remark that whilst they give good result, the first is the best; we shall not, therefore, quote any further.

We have also received a communication from Mr. H. Cooper, Jun., together with some exceedingly fine-toned specimens, possessing the characteristic warm blacks, which seems to be the general result of the lime bath wherever it is successfully used. We subjoin Mr. Cooper's letter:—

DEAR SIR,—Upon returning to town after a month's absence, I was delighted to see in the NEWS for the 21st and 28th of August last, recommendations from Messrs. Parkinson's and Bartholomew for the use of lime and acetate of soda for toning. From a rather limited experience with this mixture, I can fully agree with all that these gentlemen say in praise of it.

Two months ago, upon reading and hearing so much in commendation of lime for toning, I determined to give it a trial, and at first was disappointed with the results. I then, as an experiment, mixed the lime bath with an acetate one, and proceeded to tone a few prints in it, and was agreeably surprised at the magnificent tones produced, which were unequalled by anything I had met with previously: they were just the tint I had for a long time desired to obtain—a warm, purple black, without the least trace of inkiness. I afterwards made four or five baths in the following manner, and which were equal in every respect to the first one:—

6 grains of chloride of gold and sodium (containing 3 grains of chloride of gold); from 6 to 9 grains of chloride of lime; and about 20 grains of carbonate of lime (common whiting) are dissolved in 20 ounces of boiling water and left in an open vessel to cool. When cold this mixture should be only slightly alkaline. If it be strongly so, and smell pungently of chlorine, it must be placed in a dish exposed to the air and kept warm till it is in the right condition, and in making the next bath care must be taken not to use so much chloride of lime. When the lime bath has been prepared as above, add 60 grains of acetate of soda. The bath may be used soon after mixing, but is better after it has stood a few days. Do not filter the excess of carbonate of lime from the solution, but leave it at the bottom of the bottle, and when the bath is returned to it, after use, well shake it up, and let it settle again.

Some other advantages of the bath recommended are, that the prints are wonderfully free from mealiness; that the solution does not spoil by keeping, whether it is used occasionally or not; and that the variety of tones easily produced by it is very great, otherwise I should not recommend it for general purposes, as, although the purple black is very valuable for some subjects, I prefer, for the ordinary tint, a rich brown. Now, this latter tone can be as easily produced by the lime and acetate combined as by the acetate alone, or even better.

The best way to use the lime bath is to make two solutions, one as I have directed, and the other in the same manner, but

containing a larger quantity of chloride of lime. The latter bath we will call No. 2; and I will now point out one or two cases where it may be employed with advantage; first, calling the reader's attention to the fact, that no prints doctored, as I shall describe, can come up to those produced upon paper newly sensitized from a bright vigorous negative, and toned in No. 1.

Firstly, when I have a *feeble* negative to print from, I use a paper strongly silvered, and expose to the solar rays till very much over-printed; on subjecting this to the action of the No. 2 bath, it will yield a very fair print, as, on account of the strong bleaching property of the excess of chloride of lime, the lights are cleared whilst the shadows are not appreciably weakened.

The second case is when the sensitized paper has become dissolved, either from keeping or from its having been exposed to the light. By printing deeply from a vigorous negative and toning with No. 2, nearly perfect prints will be produced for the reason just mentioned.

Of both these applications I have seen some striking examples. It will be obvious to every one that by mixing the two baths in different proportions any desired effect may be obtained.—I am yours truly,
H. COOPER, Jun.

THE PHOTOGRAPHIC EXCHANGE CLUB.

WE have received a communication from Mr. Howard, the Honorary Secretary of the Photographic Exchange Club, from which we learn with regret that it is in a very languishing condition, and seems likely, unless some steps are taken to give it new vigour, to share the common fate which has attended several other similar clubs. We think this a great pity. A free and spirited exchange system is one of the most pleasant stimulants to effort in photography, giving considerable additional zest to the production of fresh pictures. What is the reason of this state of inanition? We insert Mr. Howard's letter, and invite those of our readers interested in the matter to discuss the best means for giving new life to the undertaking.

DEAR SIR,—It is with great regret that I beg to call your attention, and likewise that of the members of the Photographic Exchange Club, to its very weak pulsations; indeed, I am afraid it will cease to exist if some vigorous measures are not taken by its members to infuse new life into it.

The contributions have been few and far between for some time past, and those consisting mostly of very indifferent photographs—some very bad indeed.

This is the worst feature, and makes the duties of Secretary very unpleasant. The labour of examining, sorting, and distributing the photographs among the members is considerably lightened by the contributions being of good quality, and is likewise attended with a great deal of pleasure, but the labour becomes irksome when one has to twist and turn to make things fit and go smoothly, and downright disagreeable when rejections form one-half of the monthly letters.

The second year of the club (under the existing arrangements), being very near its termination, I have been induced to write to you with a view of some alterations, and, I hope, improvements being made, and solicit suggestions from members to that effect.

After so much has been said, read, and written, the knowledge that so much bad photography stalks through the length and breadth of the land, is very discouraging.

The club numbers among its members many good photographers, and I hope they will, by their assistance and suggestions, assist and get the club out of its present difficulties.—Yours truly,

FRANK HOWARD.

Secretary, Photographic Exchange Club.
10, Lansdowne Road North, South Lambeth.

THE MANUFACTURE OF PHOTOGRAPHIC COLLODION.

BY W. L. NOYERRE.

THERE are few photographers who make their own collodion: the reason of this is obvious. There are many commercial collodions for the photographer to select from that are found to meet his requirements. To manufacture a

uniform article requires great care; if a suitable place be not procurable, it becomes an exceedingly disagreeable operation, and it occupies time, which the photographer can generally lay out more profitably. The consequence is, that as there are few who require information on the subject, so has very little been written about it. In perusing photographic works, we find numberless formulæ for developers, intensifying agents, toning baths, and other solutions employed in the art, but very seldom do we see a formula for collodion, which, after all, is the principal substance we have to work with. What has induced me to say anything on the subject, after giving such ample reasons why the general photographer has no need of the information, is the hope that what I have to say may be acceptable to those who practise the art abroad in the tropics, and other places where good collodion cannot be purchased.

In hot climates collodion rapidly decomposes; even supposing that a sample by a good maker can be procured, and that it is in good order when it reaches the photographer's hands, which I can say from experience is seldom the case, it often becomes decomposed before the stock is exhausted, and consequently the photographer is thrown back till his next supply arrives.

Now, as the substances employed in making collodion are procurable in most countries, and if obtained from England do not decompose like collodion, the photographer may often be independent and free from the above sources of failure and disappointment if he can make a collodion for himself. Let him buy it when he can get it good, but when he cannot purchase it he should know how to make it.

Whatever formula is employed, the same general rules apply, and almost the same anomalies will be met with. There are many formulæ that may be used, each yielding a good pyroxyline; one very simple, and producing uniform results, is that given by Mr. Wharton Simpson in the PHOTOGRAPHIC NEWS ALMANAC, the pyroxyline made by it is very well adapted for bromo-iodized collodion, and by slightly modifying the formula a cotton suitable for any kind of collodion may be produced. First to be considered are the chemicals and apparatus required.

It is important that a proper place be selected for the operation, where the fumes from the mixed acids may be carried away so as not to annoy the operator. A kitchen-range answers the purpose admirably; the fire will be required to heat a saucepan of water; on the hob will be found sufficient space for conducting the operation, and the draught will cause the poisonous fumes to go up the chimney. If the operator is obliged to manipulate in an ordinary room, the doors and windows should be opened so as to produce a draught through the room and carry the fumes away from the operator. In this way small quantities of pyroxyline may be prepared without inconvenience.

A deep jar will be required for containing the acid; it is best made of porcelain or glazed earthenware. An infusion jar is very convenient, as it is provided with a handle and cover. This article and a couple of glass spatulas for manipulating the cotton may be procured at Brown's Medical Glass Warehouse, Farringdon Street. A couple of slips of thick plate glass, or two stout glass rods tied together, will also answer the purpose.

A thermometer is necessary for testing the temperature. It must be accurate, and it is a good plan to have a pair of them to compare before immersing in the acids. Thermometers are made for chemical purposes with the scale marked on the tube, or an ordinary thermometer may be used. Take one graduated to about 200°, make marks on the stem with a file corresponding with 150°, 160°, and 170° on the scale, now detach the bulb from the scale, and it will be ready for use.

Scales and weights of the ordinary kind, turning to half a grain, are sufficiently accurate for weighing the chemicals, and also for testing the specific gravities by means of the specific gravity bottle.

Taking the specific gravity of liquids is a simple operation,

and may be done either with an hydrometer or a specific gravity bottle.

To ascertain with accuracy the density of liquids differing much from one another, two or three different hydrometers are necessary, whereas the specific gravity bottle may be used for liquids of any density. One constructed to hold 1,000 grains of distilled water at 60° answers very well for our purpose. A brass counterpoise is sold with it the exact weight of the empty bottle; the stopper is pierced with a hole, so that when the bottle is filled with the liquid to be tested a portion of it is displaced on inserting the stopper, thus the bottle can be exactly filled. It must be wiped quite dry, and the temperature of the liquid should be as near 60° Fah. as possible. Supposing the liquid to be sulphuric acid, the specific gravity of which is 1.840, place the bottle of acid in one pan of the scales and the counterpoise in the other, now add weights till the scales balance exactly. We shall find that the acid weighs 1,840 grains, which, divided by 1,000 (*i.e.*, the weight in grains of pure water the bottle will contain when full), and expressed as a decimal, gives the specific gravity of the acid; namely, 1.840. In the same manner the density of all liquids, whether lighter or heavier than water, may be estimated. The weight of the liquid to be tested being divided by 1,000 and the quotient expressed as a decimal will be its specific gravity. Bottles are sold containing only 500 grains of water, which are perhaps more convenient as not being so bulky. In using this bottle the weight of the liquid to be tested must be multiplied by 2 before dividing by 1,000.

A syphon is very useful for drawing off the collodion. After it has been mixed and allowed to settle down for a few days it may be made as follows:—Procure a large flat cork and a long glass tube; the length of the syphon must depend on the size of the bottle—an ordinary 40 ounce bottle will require one about a foot long—bend the glass tube over a spirit lamp at right angles about a foot from one end of it, make another bend again at right angles, about four inches further on, so that when passed through a hole in a cork held over the mouth of the bottle one end of it will reach nearly to the bottom of the bottle, and the other will hang down parallel to it on the outside. This should be a little longer than the piece inside the bottle. Another tube, about six inches long, must be passed about two inches through another hole in the cork, and bent in the middle to form a convenient mouth-piece. Suppose the bottle to contain collodion with a residue of undissolved pyroxyline at the bottom, press the cork tightly on the mouth of the bottle and adjust the syphon so that the end of it, inside the bottle, will reach within a short distance of the residue. Place a clean bottle under the other end of the tube to receive the collodion and blow gently through the short tube, pressing the cork tightly on the neck of the bottle all the time, taking care not to shake it. The collodion will rise in the tube and run over into the bottle placed to receive it. When the collodion begins to pour the blowing may be discontinued. When sufficient has passed over, remove the cork and tubes, and the latter should be washed out with ether and alcohol. If the collodion is allowed to set in them it will be almost impossible to clean them for another operation.

THE COTTON.

The cotton should be the best American cotton if procurable, and where this cannot be obtained the formula for the acids must be modified to suit the particular sample.

Different kinds of cotton vary in the length of the fibre and in the amount of resin by which it is encased; impure samples containing much resinous matter, absorb the acids with difficulty, the air bubbles formed in pressing the tufts of cotton under the acids are not easily got rid of, so that nitrous fumes are likely to be disengaged, which cause solution of the cotton: and even if this is prevented, a longer time is spent in immersing the cotton, which should be avoided, or the resulting pyroxyline will not be uniform, the first portions of cotton immersed being more acted on

than that which is put in afterwards. With cotton containing much resinous matter, less water must be added to the acids, or in using a formula in which no water is employed, the temperature may be lowered a few degrees, the resin appears to decompose a portion of the acid, and consequently causes it to act more energetically on the cotton; thus, the purer the cotton, the weaker may the acids be used.

When a very impure kind of cotton only can be obtained, such as is met with in some parts of India, it is impossible to obtain a uniform pyroxyline from it without first removing the resinous impurity; this may be done as recommended by Mr. Hardwich, a quarter of a pound of cotton being gently boiled for two hours in a gallon of water in which has been dissolved two ounces of potash; the best kind of cotton boiled in this solution will tinge the liquid a yellow colour, showing the existence of a small portion of resin, but a very impure sample will make the solution quite brown, and such a cotton could hardly be used with safety for pyroxyline without first freeing it of its impurification; after boiling, the cotton must be thoroughly washed till the washing water is no longer alkaline to test paper; it should then be pressed between cloths and well dried, either in the sun or by hanging on a line before the fire.

Cotton thus prepared when immersed in the acids, absorbs the liquid at once, like a sponge; it would therefore seem desirable always to prepare the cotton in this way, however good in order to facilitate its immersion in the acids; the plan is, however, found to be troublesome: the cotton gets tangled and twisted into lumps in the process of washing and drying, which makes the pulling out into tufts before immersion in the acids difficult and tedious; added to which the cotton must be watched while boiling, and water added from time to time to replace that which evaporates, or else the solution would become concentrated to such an extent that the alkali would act on the cotton and render it unfit for use; consequently, the operator will not find it worth while to go to the trouble of boiling it in the alkali if he can get a cotton which he can manipulate properly, and which is tolerably free from impurities.

It will be found convenient to purchase sufficient at one time to last for six months or a year's consumption, and on using another sample, he must be prepared for a difference in the pyroxyline, unless the temperature or the amount of water in the acids is slightly varied. It must be remembered that cotton always retains a little moisture, it does not seem necessary to dry it artificially before use: but if we were to dry it on one occasion, and neglect to do so for another batch of pyroxyline, the results would be different. Linen, paper, and other substances, have been recommended for photographic pyroxyline; but Mr. Hardwich, who has given great attention to the subject, is of opinion that no material is so suitable as cotton-wool.

SULPHURIC ACID.

The best commercial sulphuric acid is well suited for the manufacture of pyroxyline. In Mr. Simpson's formula, he gives 1.840 as the specific gravity of the acid he recommends. Mr. Hardwich advises the use of a stronger acid, having a density of 1.845; this is the strength of the best acid. An acid is often sold having a specific gravity 1.836; in using this acid a little more must be used in proportion to the quantity of nitric acid given in the formula, the exact quantity can only be ascertained by experiment.

Sulphuric acid, which is too weak to use, may be concentrated by heating in a Berlin porcelain dish on a sand bath. The acid has a great attraction for water, and absorbs it very readily from the atmosphere, it must therefore be kept in carefully stoppered bottles.

NITRIC ACID.

There are three kinds of nitric acid usually met with, namely, the ordinary nitric acid of commerce, having a specific gravity varying from 1.5 to 1.45. We are deceived as to the real strength of this acid by the presence of

sulphuric and hyponitric acid, with which it is contaminated, the latter impurity giving it a yellow, or, more often, a reddish tinge; it also contains chlorine.

Pure nitric acid is prepared from the above, its specific gravity is 1.5, and it is used for analysis.

The third kind is an acid not quite so concentrated as the last named, but free from chlorine and the other impurities which are found in the ordinary acid, its specific gravity is 1.42, but is sometimes as low as 1.36; when this acid can be obtained it is preferable, the difference in price is not great, and more uniform results can be obtained with it. A mixture of nitro-sulphuric acid, in which the impure kind of nitric acid is employed will act more energetically on the cotton than if the acid was pure, although the specific gravity of the former is the highest. This is chiefly due to the chlorine, which decomposes a portion of the nitric acid. More water will therefore be required in the mixture when the pure acid is employed.

When an acid having a less specific gravity than 1.36 is to be used, more sulphuric must be added in proportion to the nitric acid given in the formula, the quantity being determined by experiment; the resulting pyroxyline will, however, be inferior in quality to that obtained with the stronger acid. A weak acid may be concentrated to a density of 1.42 by evaporation in the same manner as recommended for sulphuric acid. As advised in the case of cotton, a supply of sulphuric and nitric acids should be laid in which will last for some time, the quantity having been once determined, to produce the kind of pyroxyline desired, there will be no difficulty in making every succeeding batch perfectly uniform till the stock is exhausted.

(To be continued.)

ON THE COMPOSITION OF THE PHOTOGRAPHIC PICTURE.

BY EUGENE SAHLER.*

4th Experiment.—I precipitated in a capsule, in the dark, some chloride of silver, and washed the precipitate.

I poured on one side only a solution of bichloride of mercury, and then exposed it to the light.

The effect produced is known in chemistry; the portion in contact with the bichloride remained white, the other portion was reduced; I separated the first, and put it in contact with some oxygenated water. A combination took place with the evolution of heat, and the formation of oxy-chloride of silver, but not of mercury; the presence of oxy-chloride of mercury would have been indicated by a colouration, but the compound remained perfectly white.

Exposure to the solar rays made the oxy-chloride of silver pass, in spite of the presence of the salt of mercury, through all the degrees of colour observed during the reduction of the chloride.

The bichloride of mercury, as well as heat, prevents the oxydation of the chloride of silver, which cannot then be reduced by light; the absorption of oxygen, therefore, precedes reduction, and the formation of oxy-chloride is a transitory state, without which this reduction is not possible.

In the case of the bromide and iodide, the bromine and iodine, more fixed than the chloride, remain in presence of the oxybromide or of the oxy-iodide formed, and prevent the reduction; the intervention of nitrate of silver becomes necessary to effect the decomposition.

The anomaly presented by the chloride of silver submitted to the two physical agents, has always urged me to seek a more rational solution than that furnished by the various hypotheses admitted. The following experiment proves to me that I was not on the wrong track.

5th Experiment.—I submitted a sensitized and washed plate to the action of oxygenated water, and, after the lapse of a few minutes, I exposed it rapidly, making use of a sliding cap; the proof obtained would have required

strengthening to print positives from, but it was sharp and free from fogging.

Oxygenated water will, therefore, produce the maximum of sensibility, working dry, and instantaneity with apparatus and light in the best conditions: the film being very sensitive, must be carefully protected from light.

Addenda.—Take a weak reducing agent—very acid sulphate of iron will answer—with a concentrated solution the reduction will take place upon the whole plate; pyrogallic acid united to the salts of alumina produces the same effect—complete blackness.

Take diluted oxygenated water, having care, in pouring it upon the plate after sensitizing and washing, that it does not touch the fingers, which would be stained by traces of the reducing bath, for it forms light streaks from one end of the plate to the other. The other operations are as ordinary; after exposure, immerse the plate in a bath of nitrate—strength, 3 or 4 per cent.—*Revue Photographique.*

FORMIC ACID.

BY Z. L. GODINUS.

It is important for photographic chemists to learn to prepare formic acid themselves,—first, because they can derive great advantages from this product, and also because the diversity of results obtained hitherto appear to result only from the light impurities in this acid. For it is very difficult to obtain it pure; and as, moreover, it is extracted by numerous processes, the foreign elements it may contain necessarily cause a difference in its properties. Let us then examine these different modes of preparation, and assume the task of experimenting on them; such, probably, are the only means of solving this difficult problem.

The least convenient process consists in causing a mixture of sulphuric acid and peroxide of manganese, or of sulphuric acid and bichromate of potassa, to react upon most organic substances, such as alcohol, sugar, starch, mannite, gum, citric and tartaric acids, etc. To this end we must dilute the sulphuric acid, and heat it in a glass retort by means of charcoal. The reaction then takes place, and the organic substance undergoes complete decomposition; one portion yields water and carbonic acid, the other is incompletely oxidized and yields formic acid, which is left in the retort—the carbonic acid is given off. The impurities of the mixture are afterwards separated, and we thus obtain formic acid more or less hydrated; but this mode of preparation gives insignificant quantities of formic acid.

A second process consists in operating as follows:—Introduce into a retort of the capacity of about ten pints—

1st. Oxalic acid, commercial (C ² O)...	35 ounces
2nd. Syrupy glycerine	35 "
3rd. Water	4 to 7 "

Care must be taken not to heat it above the temperature of 245° Fah., and in this particular the same recommendation applies to the first method. A vivid effervescence soon takes place, and, as in the preceding method, pure carbonic acid is disengaged. In about four and twenty hours, all the oxalic acid is decomposed; one portion of its carbon has formed carbonic acid, and the other formic acid, which is dissolved in the syrupy glycerine (which remains quite unchanged). It suffices afterwards to add successively some oxalic acid to the mixture and distil, to obtain formic acid indefinitely, for the operation is continuous. The product of the distillation contains all the formic acid, or nearly so. It is treated with carbonate of soda, and a formiate of soda results, which is first dried and then easily decomposed by sulphuric acid diluted with its volume of water. We can thus obtain about twelve ounces of formic acid for every 35 ounces of oxalic acid employed.

A third experiment may be made with hydrocyanic acid, water, and a strong acid. The following formula will clearly explain the result which takes place.

* Continued from p. 390.

Very recently formic acid has been obtained by heating for several days, in glass receivers, oxide of carbon with caustic potassa or hydrate of potassa, slightly moistened. Sixty hours suffice for the carbonic oxide to become completely absorbed and transformed into formic acid. The reaction is as follows:—

Finally, if we desire to obtain formic acid at the maximum of concentration, we must pour the crude formic acid obtained by distilling the glycerine with the oxalic acid of which we have spoken, into a solution of acetate of lead.

The formiate of lead is very little soluble in cold water, so that it is almost entirely deposited in the course of a few hours, in the state of large crystals. It is purified by being redissolved in boiling water, which abandons it upon cooling in small prismatic crystals; we afterwards dry this formiate of lead in a long glass tube, heated over charcoal; then a current of sulphuretted hydrogen is passed over the formiate, converting the latter into sulphide of lead, and the monohydrated formic acid is condensed in the receiver provided for that purpose.

As to the properties of this latter acid, we have described nearly all of them in our previous article. (See p. 335.)—*Bulletin Belge de la Photographie.*

WALDACK AND DELTENRE'S PORTABLE LABORATORY.

BY DR. KLEIN.

FOR PHOTOGRAPHIC VIEWS.

THE employment of tents, or of dark rooms, of different forms, for out-of-door photography, is so inconvenient in the practice of this art, that, instead of being an amusement, it becomes, to the amateur, an onerous labour.

The tents employed are too large and too heavy to be easily carried about; they require a good deal of time to be fixed and repacked, and, moreover, they are very dear. Let us also add that with the least wind, the extension of the film of collodion becomes very difficult, and the negative obtained under these circumstances is very often riddled with small holes, caused by dust, or grains of sand. In consequence of these several inconveniences, the employment of tents is being abandoned, and, in their place, laboratories are employed in which the operations are performed, sheltered from wind and dust.

The various laboratories proposed may be divided into two classes:—

1st. Those into which the head and arms are introduced.

2nd. Those into which the arms only are introduced, and the operations carried on in the interior are examined through a window of orange-coloured glass, which intercepts the passage of the photogenic rays.

The first of these laboratories, among which we may specify that by Rouch, presents, moreover, this serious inconvenience, the operator is suffocated by heat and want of air. The second, on the other hand, very often do not permit of the photographic operations being easily carried on, in consequence of the restraint that the arrangement of the sleeves through which the arms are passed communicates to the movements.

The laboratory we are now about to describe presents none of these inconveniences. It permits free movements, and the operations are carried on outside.

The external dimensions of the laboratory are, height, 20 inches; width, 18½ inches; depth, 7 inches. It is furnished with dish, bottles, and support, and weighs only about 17 lbs., and is easily carried by a handle, or on the back like a knapsack.

The annexed woodcut gives a correct idea of it. The laboratory consists of a wooden box sustained by a very light

tripod. The linen screen is attached on one side to the upper part of the box, and on the other to the back, which falls so as to form a table; the screen is kept straight by a copper wire, and is furnished with sleeves. Upon the part falling at right angles forming the table, a bottom of vulcanized indian-rubber is nailed, furnished with a tube to carry off liquids. On the opposite side is found a door which, in the woodcut, is represented open. The light is admitted by a window of orange-coloured glass, in the roof of the laboratory, as well as by the door, and is thrown upon the indian-rubber which lines the table, where the collodion is applied and the development performed. The operations are examined through a pane of yellow glass fixed in the linen screen. The bath (vertical) is at the bottom of the laboratory, in a position inclined towards the operator, where also the bottles of collodion, developing solution, &c., are placed.

To make use of this laboratory, the operator introduces his arms into the sleeves and covers his head with the black screen as when focussing. The plate having been previously introduced through the door mentioned above, he proceeds to collodion and sensitize it, and these operations concluded, he puts the plate into the frame, taking care to replace it in the box after being used. The frame is then withdrawn from the box by the door and placed in the camera. The developing is performed in the same manner as the collodionizing. The white tint of the india-rubber lining of the table allows the operator to judge of the intensity of the negative, and, if necessary, of the strengthening performed immediately afterwards. The water necessary to be employed can be conveyed into the laboratory by an india-rubber tube attached to a bag of the same material, which serves as a reservoir, and is hung outside. The orifice of the tube is closed by means of an American clip.

The original idea of this portable laboratory belongs to Mr. Coleman Sellers, of Philadelphia. Notable alterations in it have been made by Messrs. Waldack and Deltenre, who, by means of ingenious improvements, have made it an indispensable *vade mecum* for the travelling photographer, both for dry and wet processes, by which he can satisfy

himself of the success of his picture on the spot by means of development. It may also be turned to excellent account at home in taking portraits, as it contains in a small space the materials and products necessary for operating.

This light, commodious, portable, and economical laboratory will not be long before it is in the hands of all photographers and amateurs, to whom it will render valuable service.—*Bulletin Belge de la Photographie*.

[From the stereograph of this dark box, with which Mr. Waldack favoured us, it appears to be one of the most convenient arrangements we have seen.—Ed. P. N.]

PHOTOGRAPHY ON WOOD.

BY M. EUGENE BAROUX.

ENGRAVING on wood, as is well known, requires two operations: 1st. The design is drawn upon a block of box wood, the surface of which is whitened with white lead: 2nd. The wood is then cut with the engraving tool in the whites, leaving the black lines in relief. The fidelity of a reproduction depends therefore upon both draughtsman and engraver. We substitute a photographic picture for the pencil drawing, on the boxwood itself, and thus obtain a fidelity, a delicacy of detail, an interpretation of the lightest shades, a perfect resemblance in fact to which the most skilful hand cannot attain.

This photographic picture is very distinct, the whites of the model are quite white, and the blacks very black, all the tones and half tones are perfectly distinct, and the minutest details are reproduced with the greatest exactness, however complex they may be, as well as the complete series of tones in their gradation. Hitherto, on the contrary, we have obtained on the block only a photograph without any whites, brown in every part, so that the engraver had the greatest difficulty to find a guide to his tool. All the details, in lines and in tints, traced or modelled, are thus found upon the wood, the engraver can render or neglect them at pleasure, according as he desires a more or less finished work; this is a question of time and cost.

The picture may be obtained of the same size as the object, or diminished, or enlarged, in any desired proportion.

An evident imperfection was the reversing the position of objects, in which the right became left and *vice versa*; thus a decoration, a scar, or the wing of a building were placed on the wrong side, destroying the integrity of the work, and reversing all the effects of light. By our process, we can at pleasure take the picture reversed or not, according to the exigencies of the case.

We can also take it from nature or from a photograph, or an engraving, or even an oil painting.

The whites of our picture are very solid, and like the rest of the picture resist the friction of the hand. Yet, if we wish to cancel a picture to substitute another, we have only to rub the surface with a piece of wet rag, and recommence on the same piece of wood.

If the attempts hitherto made have been unsuccessful, it is because the treatment of the wood by photographic substances rendered it unsuitable to receive the graving tool.

Very frequently the wood, the yellow colour of which is so necessary to the engraver, is found to be black or brown to a certain depth, or at least impregnated with substances which exposed by the cutting tool, quickly blacken in the light. Then the ground of the hollows becomes confused with the design being also black, from whence arises confusion of lines, undecided outline, and great difficulty in following the operation of the graver with certainty. And after the first-proof which can only be obtained by blackening all the parts in relief, nothing is perceptible but a uniform black tint, where retouches are impossible.

In our method, on the contrary, the wood is not attacked, not even on its surface, but shows everywhere its natural hue, so that the burin, by the lightest touch, removes the photographic film.

And this film is extremely thin. That is an indispensable condition; for, without it, the tool would attack the

wood only through the photographic design which must be removed before taking proofs, the wood, thus stript is found to be insufficiently hollowed, consequently too black, and leaves too much to be retouched.

We sometimes have a photographic coating that is too soft, which tears instead of cutting sharply under the tool; sometimes it is too dry, then it scales off at the slightest touch of the graver.

Frequently the photographic film forms a glossy surface like tissue paper, over which the pencil glides without marking, rendering all correction impossible. Upon our picture, the crayon marks vigorously; we can, therefore, correct and modify the model, and mark the lines if necessary, although a skilful engraver will not require them, his practised burin preferring the free and initiative essay, contenting itself with the indications of the various hues. According to circumstances we may mark a retouch with blacklead, indian ink, or the stump.

The engraving completed, if before taking a proof, we have not sufficiently cut into the wood, it will acquire in the light a reddish hue in the cut portions. We must not conclude from this that it is attacked, if it has not reddened during the engraving. It is an effect of the re-vivification of the sensitive film by water. To avoid it, it is only necessary to wash the block with a brush and spirits of wine in the dark.

Our block thus engraved gives casts with the same facility as ordinary engravings, and with more certainty, because it is hardened by our preparatives, as we have remarked in our various *cliches*.

COLOURED PHOTOGRAPHS.

M. DE LUCY recently presented to the Paris Photographic Society several paper positives obtained with various colours by means of chemical reactions in the fixing baths. He accompanied them with the following communication:—

"I do not pretend to make a *colouring after nature*, such as I hope we shall some day obtain direct upon a sensitized film. I leave the search for this to inquirers more competent than myself to carry them to a successful issue. My aim is quite different, and may be briefly stated as follows:—

"Professional photographers know how difficult it is to satisfy the public, and especially ladies: many of whom, dissatisfied with a simple black and white photograph, insist upon having them coloured.

"But the painter's colour, however light and well-managed it may be, very often conceals the photographic picture, and even causes the resemblance to disappear sometimes. I seek to remove this inconvenience by producing, through chemical means and the aid of different *colourless* salts, an intimate colouring, directly incorporated with the paper or the film of albumen, and which, consequently, allows the photographic picture to appear in its original integrity.

"The colours produced are the result of the combination of the salt employed with the chloride of silver of the paper. Although I have as yet operated only with a very limited number of salts relatively to an enormous number of salts known. I have been able to remark, as may be easily understood, that the alkaline and metallic *chlorides* have always yielded better results than other salts.

"I employ in preference the chlorides of sodium, potassium, calcium, gold, mercury, cobalt, iron, tin, &c.

"Among the other salts, acetate of lead, and cyanide of potassium have yielded very good results.

"My usual mode of operating is as follows:—When the proof is printed, with the aid of a pencil I place on that portion of the proof I desire to colour a very weak and colourless solution of the salt which will give me the wished for hue, and I leave it to dry in the dark; then the proof is placed in the toning bath with the others.

"This supplementary work, which consists in moistening this or that part of the proof, presents no difficulty and is performed very rapidly. I have had to prepare in this

manner two hundred cards a day, and the work was performed in less than an hour by a girl of fourteen.

"The blue colour I obtain with the pink chloride of cobalt rapidly disappears in cold, damp weather, but if the proof be slightly warmed the colour re-appears. I may also state that for toning I employ a mixture of 1 gramme of gold and 8 litres of water (15 grains of gold to 14 pints of water)."

—*Bulletin de la Société de la Photographie Française.*

ON A NEW METHOD OF MEASURING THE CHEMICAL ACTION OF THE SUN'S RAYS.

BY DR. T. L. PHIPSON, F.C.S. LONDON, &c.*

THE exact determination of the chemical action of the sun's rays is an important and interesting question which concerns especially physiology and photography, as well as agriculture, &c. Quite recently I have been fortunate enough to discover a means of measuring this action each successive day with the greatest accuracy, and have reduced this determination to a single chemical analysis by the volumetric method.

Many attempts, more or less successful, have been made to solve this problem. Some years ago, Dr. Draper, of New York, used for this purpose a mixture of hydrogen and chlorine, and observed the amount of absorption each day when this gaseous mixture was exposed to diffuse daylight. This method doubtless gives accurate results, but it is not easy, and requires a special apparatus. M. Niepce de St. Victor attempted the same thing in 1858, by means of a solution of nitrate of uranium and oxalic acid. This mixture exposed to the sunlight evolves a gas, the volume of which may be measured; but no experiments have been instituted to test the accuracy of this method. I have myself experimented with a mixture of iodide of silver and starch, but am not quite satisfied with the results. More recently Professor Roscoe has devised an ingenious apparatus—a sort of photographic pendulum—but the basis of the observation consisting in the darkening of a photographic paper (however carefully prepared) is not altogether satisfactory in a scientific point of view. I happened lately to notice that a solution of sulphate of molybdc acid (that is, a solution of molybdc acid in excess of sulphuric acid), standing in my laboratory upon a shelf which is exposed to the sun for about three hours each day, became bluish green in the daytime and colourless again at night. I repeated the experiment several times and found that the saline solution, when exposed to the sun, was reduced, but when withdrawn from its influence it gradually becomes colourless again by oxydation.

No evolution of gas is observed. During the insolation a certain amount of molybdc acid loses one atom of oxygen, which combines with the water and forms oxygenated water. During the night this gives back its oxygen to the molybdc oxide produced. The reaction may be represented thus:—

The whole being in presence of an excess of sulphuric acid.

Nothing is easier than to measure with the greatest accuracy the amount of reduction which takes place by the sun's action in a given time. Let it be stated immediately that the change is not influenced by the heat of the sun's rays, for the same solution boiled for some time manifests no change of colour. A weak solution of permanganate of potash destroys the greenish blue tint produced under the influence of the sun's rays, and from the quantity of permanganate solution employed the relative amount of actinism on each successive day may be determined.

The manner in which I prepare the actinometric liquid is as follows:—About 10 grammes of molybdate of ammonia are dissolved in an excess of dilute sulphuric acid. I then introduce metallic zinc until the liquid has become dark blue or

greenish blue; a solution of permanganate is added carefully until the last drop restores the liquid to its primitive colourless state. A provision of this liquid having been made, 20 cubic centimetres are exposed to the direct rays of the sun for one hour each day (from 11 to 12). It is then withdrawn, and the amount of reduction estimated by a very weak solution of permanganate or bichromate of potash of known strength. I prefer a solution made by dissolving 0.25 to 0.50 of a gramme of permanganate in 1 litre of water acidulated with a little sulphuric acid. I make use of a pipette, having a very thin stem graduated into 100 equal divisions. The degree read off on this scale represents for each day the relative amount of actinism, as the thermometer indicates the degrees of heat. I have not yet made a lengthened series of experiments by means of this method, but I find already that the variation of the actinism describes curves which are not only irregular; but sometimes present sudden deflections of great extent similar to what is observed in the barometric curves, to which the former may possibly be related.

P.S.—Since this note was communicated to the British Association I have been seeking a more rapid method, based upon the same principles, but more fitted to the requirements of the photographer. It will be seen that the above means of proceeding is very exact for scientific purposes, and the process is not difficult. We have only to be careful in taking always the same amount of substances to prepare the two test liquors, and to expose for the same length of time. I shall probably be able to replace the molybdc solution by one of oxalate of peroxide of iron, which I showed some time ago to be capable of replacing nitrate of silver in photography.

PHOTO-ELECTRIC ENGRAVING AND OBSERVATIONS UPON SUNDRY PROCESSES OF PHOTOGRAPHIC ENGRAVING.

BY DUNCAN DALLAS.*

I FEEL that an apology is due to the Association for bringing under their notice some results of my process of photo-electric engraving, without, at the same time, describing in full detail the method by which the results have been obtained. Were it not for the more than questionable protection afforded by our patent laws, or were I the possessor of ample means, I should be glad to allow my little rill of applied science to flow unrestrained into the great stream of knowledge, of which your Association is no mean tributary. I regret that at present I must place somewhat of a dam across my little rivulet, and permit but a slender portion to trickles over. I have sacrificed, much in time, money, and position, to the "idea" of engraving photographs. If I have now solved the problem with some degree of success, I am naturally anxious to reap a return for well nigh nine years' exertions, during which the subject has occupied no slight portion of my thoughts and the labour of my hands. At a future day I hope to submit a proposal, which, if agreed to, will enable others to work, and, very possibly, improve my process.

The specimens I now submit must speak for themselves. They have received no aid from the graver. Each plate has passed under the hands of a skilled engraver, but merely for the purpose of careful cleaning. Not a single detail, or half-tone, has been introduced by tool work, nor have the vigorous parts been "doctored" with acid or the roulette. The impressions show honestly the result of the process. I am glad to be in a position to say, that, unless my head or my hands fail me, the system is certain. I can guarantee to produce, in a period varying from one to three weeks, an engraved plate, either from a photograph, or the design of the artist. In this plate, that which constitutes the essence of the original and the despair of hand labour—*fac-simile*, even to minute and almost microscopic detail, should be present. To attain this result, all that I require is a good reversed negative—easily produced by reversing the glass—and a positive print, merely fixed in the hypo, not

* Abstract of a paper prepared for the British Association for the Advancement of Science, at Newcastle. This paper was deemed inadmissible by the Chairman of Section B, as relating to a secret process. It contains, however, matter which will interest our readers.

* Read before the British Association. (See Section B.)

toned. Having but lately emerged from the purely experimental stage—for I still experiment—I have not had time to get up many specimens. Beside the "Banqueting Hall," Kenilworth, (kindly taken for me, on purpose, by Mr. Bedford,) I should have been glad to have placed a reproduction of a good drawing or a highly finished sketch—something done by a Landseer, a Millais, or other eminent artist. I have just commenced a subject of the kind, viz., a sepia drawing, by a well-known artist, who takes an interest in my operations. I do not fear but that I shall reproduce his drawing, touch for touch, preserving the spirit and beauty of the original—a result impossible to hand-engraving.

As all persons now present may not be fully conversant with what has been done in photographic engraving, I would ask permission to say something on the subject. There have been four principal efforts to solve the problem of producing an engraved photograph.

- I. Etching daguerreotype plates.
- II. The bitumen process.
- III. Photography.
- IV. Photogalvanography.

The methods of photolithography and photozincography are not engraving, but more properly transferring processes. From their very nature they can never rival plate-printing. Valuable as they are, undoubtedly, for some purposes, they will in all probability always lack even half-tones, minute detail, and unbroken, clean-edged lines.

Of the four engraving processes above mentioned, the first three are essentially etching methods, while the fourth is an electrolytic process. Those which have given most promise are the bitumen process, photoglyphy, and photogalvanography. The bitumen process and photoglyphy being decidedly etching methods, involve much hand labour. Consequently, it is impossible to ensure fidelity, either in tone or detail. Photoglyphy is the least satisfactory of the two. The etching ground being gelatinous is of a most delicate nature, and the photographic chemical, bichromate of potash mixed with the gelatine has the unfortunate quality of destroying the half-tones and detail the longer the combination is exposed to actinic influence.

Photoglyphy was the name given to a second patent taken out in 1856 by Mr. Fox Talbot, for improvements in his former patent of 1852. There is very little real difference between the two patents. They may therefore be considered as one. That of 1852, entitled Photographic Engraving, is certainly deserving of the merit of striking novelty and great ingenuity. In short, it bears the impress of genius. But, like many other promising and apparently simple processes, it is beset with practical difficulties which have never yet been successfully overcome, but which, from their very nature, operate to produce failure.

While I acknowledge Mr. Talbot's genius, justice compels me to add that his patent has placed him in much the same false position with regard to photo-engraving which his original photographic patent did in reference to the collodion process. It has made him the foe rather than the friend of photographic progress. Indeed, as regards photo-engraving in this country, the present patent laws afford a striking illustration not only of how little they advance science and art, but how greatly they hinder the development. Nine-tenths, if not ninety-nine hundredths of existing patents are either dormant, impracticable, or mere advertising shams. Many patentees either cannot or do not work their patents—nor will they permit others to work them. Such persons are ill entitled to the honour of using the royal arms. Messrs. Cruikshank and Leech might furnish them with a more appropriate heraldic device, say a dog, *latrant*, in a manger, *argent*—supporters, a tortoise and a sloth; the motto, *Noli me tangere*.

It is to be hoped that ere long the present system will receive its death blow. The British Association can do good service. Inventors are unquestionably as much entitled to copyright in the fruits of their brains and hands as the novelist, who, in these halcyon days, obtains fabulous sums as his guerdon. Nay more, the novelist chiefly tickles the fancy. The inventor increases the wealth, power, and happiness of the State. Still no inventor ought to have the power of preventing others from using his invention when willing to pay a reasonable royalty. Even with the existing patent law, it would not only save an immense amount of litigation, but positively advance the arts, were patentees obliged to grant licences at amounts to be

arranged, in case of dispute, by arbitration. Infringements are chiefly occasioned by the selfish exclusiveness of patentees.

I have been led into these remarks in consequence of my experience in my former association with what promised to be the most important advance in photo-engraving. I allude to photogalvanography, a process which owes to me not merely its name, but its reduction to a practical process, and its introduction as such to the public. It is useless to assert, as has been attempted, that this discovery was completely independent of Mr. Talbot's invention. Not only are dates against the assertion by two years, but I am acquainted with facts which leave no doubt that experiments with Mr. Talbot's process led to the discovery.

The essential feature in photogalvanography is the production of a raised image in gelatine from which an intaglio plate has to be produced by the electrolytic process. Now Mr. Fox Talbot discovered this raised image, and it forms the most beautiful feature in his invention. Strangely, he completely overlooked its value, not even including it in the extraordinarily wide claims at the close of his specification. He merely contented himself with admiring its novelty and beauty, while expressing his regret that he was obliged to destroy it in order to effect the only object of his invention, viz., to etch through the image to the plate. When photogalvanography first came under my notice, about nine years ago, I was quite ignorant of Mr. Talbot's labours above mentioned. I was, therefore, much surprised when, early in 1855, I became acquainted, through "Hunt's Photography," 1854 edition, with the details of Mr. Talbot's process, and found points, especially the production of a raised image, so strangely identical with photogalvanography. Being, however, most solemnly assured that the latter process had derived no assistance whatever from Mr. Talbot's discovery, and that the first intelligence of the existence of such a method of engraving was the passage in "Hunt's Photography" which I had just read aloud, I regarded the matter as one of those remarkable coincidences in which two minds arrive independently at analogous discoveries. My surprise, however, gave place to a different feeling when, in 1856, Mr. Talbot first threatened to interfere with the operations of the company I had formed for working the photogalvanographic process. I then made the unwelcome discovery that Mr. Talbot had patented his process, and that long previous to the photogalvanographic patent he had fully described his method in the *Journal of the Photographic Society*, the *Comptes Rendus*, and, I believe, in *La Lumière*.

Photogalvanography like photography, depends on the peculiar action of bichromate of potash with gelatine. In this lies its weakness. It loses half-tone and detail, the more so as it requires a very long exposure. Sometimes the exposure is upwards of six hours, and even then there is no certainty that the right time has been hit. There are, consequently, numerous failures from this one cause alone.

From a series of experiments I conducted with the process, I found that chromic acid was in reality the agent producing the peculiar phenomena. In other words, that with a composition merely of chromic acid and gelatine a raised image with granulation could be produced and subsequently electrolytically. Independently, however, of the loss of half-tone and detail, together with the uncertainty of the exposure—both defects inherent in the process—the granulation was of a peculiar zig-zag and wavy character of great value in the vigorous parts of the picture, but broken or unconnected in the half-tones and fine details. This led to a pretty free employment of the graver and roulette just in the very parts which made hand labour expensive. The process, indeed, was never capable of the high flight which was attempted; and, as I had predicted, it broke down. It was an effort to run, and very fast too, before the bantling had learnt to walk. Where expense was no object, the graver and roulette were a great assistance; but besides lessening the value of the fac-simile, it was a fraud on the public to represent the highly worked up result as photogalvanography. Since the abandonment of the process by the company, other firms have endeavoured in connection with the patentee to render it available. But without expensive assistance from the graver it cannot be used for fine art purposes; and even when highly worked up, the result cannot be said to be perfectly satisfactory. I believe I am well qualified to give an opinion of its true capabilities. It is still a most uncertain process, and on this ground also it is expensive. It gives, however, such a strong grain, that in subjects with broad contrasts, it is valuable. It also renders lines

possessing equal vigour in a very fair manner, but if there is contrast in the lines—very fine and delicate with stronger forms—the defect inherent in the process comes out disagreeably. The longer the light acts, the sooner do the finest lines disappear, and those next in degree become broken. It is the same with dots. Indeed, the disappearance of the finest parts commences with the first action of the light.

It is not with a view to cry up my own process, that I would decry photogalvanography. As I have said, I should have no qualm in working the process, and that without fear of Mr. Talbot's patent, or still less of the photogalvanographic patent itself. But as I can do by my method at a rate as cheap if not cheaper, what pure photogalvanography does at its best, I am merely stating what I am in a position to prove as a fact.

The bitumen process has been chiefly practised in France, but all the specimens produced bear evidence of considerable graver work and finish. As an etching process, there is no question as to its superiority over photoglyphy. It has also the advantage over photogalvanography of a more perfect rendering of the half-tones and detail; but it requires a great amount of hard labour in the intermediate tints and vigorous parts of the subject.

Etching daguerreotypy plates is hardly worthy of mention, as so little has been done with the process. In these days when "impossible" is a hazardous word, I should be sorry to say that it will never prove useful. At present, however, its chances appear very remote.

In the bitumen process, photoglyphy and photogalvanography, the results are obtained from a positive impression. This is in many respects a desirable advantage.

Photo-electric engraving, the specimens of which are now before you, is, as its name imports, an electrotype process. In the photographic part it is as absolutely certain as the collodion process. Its success depends like that process upon the careful dovetailing of three or four main operations, to neglect any of which, or to perform them amiss, is certain failure. The objects I had in view were two-fold:—

I. To obtain a process based on the negative.

II. To produce in the resulting metal-plate the effect of a combination of aqua-tint and stipple.

In the methods which have been adopted (and I believe patented) of building up on the collodion surface there is great risk of injuring the negative. This is a serious defect, involving the taking of another negative—a thing not always practicable. In my process no injury is done to the original negative.

Any one acquainted with engraving is aware that aqua-tint and "chalk," or stippling, produce fine grain, even half-tones, and minute detail. The aqua-tinter employs common resin dissolved in spirits of wine. This poured over his plate, evaporates and leaves numerous globules or bits of resin attached to the surface. The size of these globules depends on the proportion of resin to spirit. When the acid is put on the plate the resin acts as a resist, and a tint is produced in the intermediate parts. If the plate were now electrotyped before the removal of the resin, and a print taken from the electrotype, the resin parts would give a kind of stipple or chalk marks interspersed with tint. It is something similar to this which I have succeeded in imitating, with peculiarities *sui generis*, by photography and the electrotype. I can also, as it were, modify the size of the dots, obtaining them so fine as to carry almost microscopic detail; but, if too fine, there is a risk of deficient depth in the darks. In this, as in all things, there is the happy medium, and this I believe I have secured.

I commence with a varnished negative. This should be reversed, but not necessarily so, for some purposes. From this negative a positive print is taken. This I prefer not toned but merely fixed in the sepia colour by the "hypo." I cover the varnished negative with a material from which I obtain a latent positive. This latent positive I turn by a simple process into a suitable negative. It is with this negative that I subsequently manipulate. I can time the exposure to a nicety, a few seconds over or under making an inappreciable difference. The excess or deficiency must not, however, extend to minutes. If necessary, I can electrotype direct upon my material; but as this might lead to the discovery of part of my process, I prefer to make a different kind of matrix.

I should have been glad to have taken out a patent, with a view to grant licences; but, as the lawyers say, no patent is valid till well litigated. I prefer to run the risk of competition, which, after all, is of more benefit to the arts and to commerce

than such inconsistent monopolies as the present patent laws permit.

In the course of my investigations, during which I may safely say I have performed some thousands of experiments, I believe I have gleaned some interesting, if not important, photographic and chemical facts. It is, I can honestly aver, a source of regret to me that I am not at present able to add my mite of knowledge to the general fund. It is a noble employment for a man possessed of means and leisure to enlist both in the advance of science and art, regardless of thereby increasing his worldly estate. But when a man has spent some of the best years of his life in battling for an object, and sees at length most of his difficulties surmounted at no small cost to his means, to say nothing of his leisure—scanty at the best—it becomes, I think, his paramount duty to "let charity begin at home." The man of means and leisure has received freely—freely let him give. The other must protect himself as best he can, for the law affords him no safeguard against men who, perhaps, never gave ten minutes' thought to search out and apply scientific facts. On the contrary, the law affords such persons every facility for sucking the brains of those who think and work. These considerations must be my excuse for my present reticence. It is also no idle assertion when I state that had I not taken up as earnestly as I have the "idea" of engraving photographs, I should be some thousands of pounds in pocket.

In concluding this paper, which, I fear, has been too long, I would observe that in my process the perfection of the result depends essentially upon the perfection of the original—the more highly finished the latter, the better adapted to my purpose. There is also another important advantage. It is not very much more expensive to work from a good original than from a bad, or inferior one. Though cheaper than second, or even third-rate hand-engraving of a similar class, it is principally as compared with the better styles of engraving that the great cheapness of the process becomes apparent. The saving varies from 25 per cent. to 50 per cent., and upwards. When desirable, special engraved effects can be introduced without injury to fidelity of detail. They would be chiefly of an artistic character—especially in the play of light and shade, or improvement in prints, in which even the best of photographs require attention. For example, in the Kenilworth subject before you, a sky might be introduced, and the foliage in the trees on the right, and other blurred parts, might be made out more clearly. My plates thus afford the artist engraver a valuable basis on which to work; and not only is a great part of his labour and skill anticipated, but he can be outdone by Nature's own touches and effects, or by the brush and pencil of the painter rendered in *fac-simile*.

I beg to thank you for the kindness with which you have listened to me on the present occasion.

British Association for the Advancement of Science.

REPORT OF THE KEW COMMITTEE.

The great importance of photography as a scientific registrar receives annual illustration in the report presented by the Kew Committee, of which we append an abstract.

It commenced by recording the fact that, under the superintendence of the committee, a set of self-recording magnetographs had been constructed for the Lisbon Observatory. These instruments had arrived at their destination, and since July 1st had been in continuous operation, copies of their tracings from July 11th to 16th having been received, during which period a magnetic disturbance had occurred simultaneously at Lisbon and Kew. These tracings, with the corresponding Kew curves, are exhibited to the Association.

The committee have likewise been requested to superintend the construction of a set of self-recording magnetographs for Professor Kupffer, of the St. Petersburg Central Observatory. These were constructed as before, the magnetographs by Adie, and the tabulating instrument by Gibson; and after having been verified at Kew they were despatched to St. Petersburg. Professor Kupffer desired also a differential vertical force magnetometer for Pekin, which has likewise been constructed by Adie, and verified at Kew; it remains in readiness to be forwarded by the first suitable opportunity to its destination. In addition to

these instruments, Professor Kupffer is obtaining from Adie a barograph and a self-registering anemometer, both of the Kew pattern. Professor Kupffer proposes visiting Kew in October, for the purpose of acquainting himself with the mode of working the instruments adopted there.

Mr. CHAMBERS has communicated to the Royal Society a paper "On the Nature of the Sun's Magnetic Action upon the Earth," in which it is argued that, in causing the daily variation, the sun does not act as a magnet.

The CHAIRMAN has procured a spectroscope affording very great angular separation, which remains at Kew; and he has also ordered a heliostat from Paris. By those means it is hoped that the minutie of the solar spectrum may soon be examined with great facility.

The solar spots are now regularly observed at Kew, after the method of Dr. Schwabe, of Dessau, who has been communicated with, and will be written to from time to time, in order to ensure that both observers pursue exactly the same method of observation. It will be remembered that in the report of the committee at the Cambridge meeting it was stated that Mr. De la Rue had taken 177 photographs of the sun, and that the number of available days from February 7th to September 12, 1862, was 124. The Kew heliograph was worked at Cranford up to February 7, 1863, and photographs were procured on forty-two other days between September 12, 1862, and February 7, 1863, making 166 working days in the whole year. The series of negatives are now in course of measurement and reduction by Dr. Von Bosc; the micrometer employed is the same as that constructed for, and used in, the measurements of the eclipse-pictures obtained in Spain in 1860, a detailed description of which instrument is given in Mr. De la Rue's paper in the *Phil. Trans.* vol. clii., pp. 373 to 380. Of the 1862-1863 series, the measurements are finished up to the end of June, and the reductions to the end of April, 1862; both will be completed at the end of this year. In February of the present year the heliograph was removed from Cranford to the Kew observatory, and erected again in the dome. A new and commodious photographic room has been built on the roof of the observatory, close to the dome, and has been fitted up with the requirements necessary for the successful prosecution of astronomical photography. The expense of this room has been defrayed out of the sum of £100 granted for that object at the Cambridge meeting. The actual sum expended up to the present time amounts to £89, leaving a balance of £11, which will cover the outlay for a few pieces of apparatus which are still required. Between February 7th and May of the present year pictures of the sun were occasionally procured at Kew; but the heliograph could not be fairly got to work until the completion of the photographic room and the final adjustment of the instrument itself. From the 1st of May to the present time the heliograph has been continuously worked by a qualified assistant under the immediate supervision of Mr. Beekley. Two photographs are taken on every working day, one to the east, and the other to the west of the meridian, when atmospheric conditions permit of this being done. From May 1st to August 14th inclusive, are been fifty-four working days. Four positive copies are made regularly from each negative, one of which it is proposed to retain at Kew, and it is in contemplation to distribute the others. Mr. Stewart, after an inspection of all the sun pictures obtained by the Kew heliograph, is inclined to think that the behaviour of solar spots with respect to increase and diminution has reference to ecliptical longitudes, and is possibly connected with a position of the nearer planets: but it will require a longer series of pictures to determine this than that which has yet been obtained. The heliograph constructed by Mr. Dallmeyer for Wilna, under Mr. De la Rue's superintendence, has been completed, and will shortly be sent to Russia, together with a micrometer and protractor constructed by Messrs. Troughton and Simms, which will be employed in the measurement and reduction of the sun-pictures. Of the £150 granted by the Association in 1861 for the purpose of obtaining a series of photographic pictures of the solar surface, a sum of £137 3s. has been expended from February, 1862, to February, 1863, and the balance, £12 17s. has been returned to the Association. In 1860 a sum of £90 was voted for an additional photographic assistant, of which £50 was received and expended in that year. The balance, £40, was again granted in 1861, out of which £20 2s. 10d. have been expended. The working of the Kew photo-heliograph during the year commencing in February, 1863, will be defrayed out of a grant placed in the hands of Mr. De la Rue by the Royal Society for that purpose.

ON SOME PHENOMENA PRODUCED BY THE REFRACTIVE POWER OF THE EYE.

BY A. CLAUDET.

The object of the paper was to explain several effects of the refraction through the eye, one of which is, that objects situated a little behind us, are seen as if they were on a straight line from right to left. Another, that the pictures of external objects which are represented on the retina, are included in an angle much larger than one-half of the sphere at the centre of which the observer is placed; from this point of view a single glance encompasses a vast and splendid panorama extending to an angle of 200°. This is the result of the common law of refraction. All the rays of light passing through the cornea to the crystalline lens are more and more refracted in proportion to the angle at which they strike the spherical surface of the cornea. Consequently, the only objects which are seen in their true position are those entering the eye in the direction of the optic axis. By this refraction the rays which enter the eye at an angle of 90°, are bent at 10°, and appear to come from an angle of 80°. This phenomenon produces a very curious illusion. When we are lighted by the sun, the moon, or any other light, if we endeavour to place ourselves in a line with the light and the shadow of our body, we are surprised to find that the light and the shadow seem not to be connected at all, and that, instead of being in a line, they appear bent to an angle of 160° instead of 180°, so that we see both the light and the shadow a little before us, where they are not expected to be. The eye refracts the line formed by the ray of light, and the shadow and the effect is like that of the stick, one-half of which being immersed in water, appears crooked or bent into an angle at the point of immersion. This enlargement of the field of vision to an angle of 200°, is one of those innumerable and wonderful resources of Nature by which the beauty of the effect is increased. Our attention is called to the various parts of the panorama which appear in any way a desirable point of observation, and we are warned of any danger from objects coming to us in the most oblique direction. These advantages are particularly felt in our crowded towns, where we are obliged to be constantly on the look-out for all that is passing around us.

INVISIBILITY OF LIGHT.

The Abbe Moigno exhibited and explained the "Tenebroscope" invented by M. Soleil to illustrate the invisibility of light. The Abbe humorously observed that this term was somewhat of an Irishism, but nevertheless it was a fact that light is quite invisible, for celestial space was perfectly dark until the appearance of a celestial body, and then it became perfectly illuminated. The instrument for illustrating this consists of a long tube, closed at one end, but with a short opening in the centre, in which is introduced a white ivory ball, capable of being placed and withdrawn at pleasure. The object of the instrument is to illustrate the principle that light is only the action of a luminiferous medium by which bodies are made visible; and that neither the light itself or the medium is visible. On looking through the glass with the ball withdrawn, no light is seen, but immediately on the ball being replaced, it is distinctly seen at the end of the tube. The president said this principle was first laid down by Aristotle, that light is the action of a luminiferous medium, whereby bodies are made visible. Neither light nor luminiferous medium are visible, but require the introduction of a body to make the light manifest.*

ACTINIC CONDITIONS AT A HIGH ELEVATION.

Professor C. PIAZZI SMYTH called attention to the increased dioptric and actinic quality of the atmosphere at a high elevation as illustrated by his photographs on Tenerife. If, he said, a photographic landscape were taken at the sea level, and if in the view there were included some distant hills, it would invariably be found that those hills would be represented only by the faintest aerial impression of a perfectly uniform tint; and though the examination were pursued with a good compound microscope, nothing further would be ascertained—no matter if the sun were shining brightly at the time the photograph was taken, and the hill itself was marked by well-defined irregularities, not one of them appeared in the picture.

* We have been amused occasionally by observing in articles in some of the journals on "lighting," the statement that light was opaque. It will be seen at once that if light be invisible it cannot be opaque.

But when a similar view was taken at an elevation of from 5000 to 10,000 feet a distant hill, forming part of the mountain range, was perceived with all its details, at a distance of four miles or five miles and a half from the camera; and when a good microscope was applied to the picture at once, they found the same projecting mountain, and saw what not merely the ridges and hills, but the valleys, rivers and lakes upon the distant hill sides. At a height of two miles above the sea level the actinic rays by which the photograph was produced experienced less disturbance at the long distance than when at the sea level they had to penetrate only 200 or 300 feet of the denser atmosphere. He has inclined to believe that one great agent in producing this remarkable degree of definition of minute distant features was the steady, uniform current and more equal temperature prevailing at the greater elevation. The effect of this might also be ascribed to the improved brilliancy of the stars when seen from a considerable height. There were few nights in which, at the sea level, the highest power of the astronomical telescope could be employed; but the case was altogether different when the observations were taken at great elevations.

The repeated tracing of these remarks was to indicate the importance of establishing the observatory at a great height above the sea level.

Mr. GLAISHER made some extraordinary observations. His own experience was that were an observatory placed at a high elevation, more discoveries might be made in one year than would be made in a hundred years by observatories placed on a low elevation. He had then earnestly wished that an observatory could be placed—perhaps, if possible, but even first of all—at some high elevation. He made the Association were much indebted to Professor Piazzzi Smyth for the noble manner in which he had made his observations on the Peak of Teneriffe, and submitted them at different times to the meeting. (Applause.) He trusted that, before long, some of the other eminent astronomers might be induced to ascend to the same elevation and prosecute important investigations. (Applause.)

The President, in moving a vote of thanks to Professor Smyth for his important communication, also expressed the hope that, before long, another expedition of scientific men would be completed to the Peak of Teneriffe.

The photographs exhibited were from enlargements of small negatives, some being enlargements upwards of five hundred and others upwards of one thousand. They consisted of illustrations to the recently issued Astronomical Observations made at the Royal Observatory, Edinburgh, edited by Professor G. P. Smyth. They were views of a mountain, 4½ miles distant, clearly taken at a height above the sea level of 10,700 feet, the object being well made out. One print was from a negative taken at the sea level with the same camera lens, camera, &c., and so forth under the same conditions, except altitude. This was thirty times as dirty as the other. One of the prints was a photograph by Mr. Fox Talbot, which presented many good qualities.

PHOTOLITHOGRAPHY, &c.

The Allen Medal exhibited a section B some specimens of photolithography, which presented a certain amount of brilliancy. The process was invented by M. Mangelier; but in what its superiority consists the Allen did not make clear.

Some other papers, interesting to photographers, were given in their entirety on another page. The sessions of the Association will be held next year at Bath.

Correspondence.

FORMIC ACID AN ACCELERATOR.

SIR.—Being a constant reader of your valuable periodical, I could not help noticing the discrepant opinion as to the accelerating effect of formic acid in the negative developer: desirous of judging for myself, I have commenced a series of experiments. As yet I have only tried it in combination with pyrogallie acid and with bromo-iodized collodion, and from these experiments have arrived at the following conclusions, namely, that formic acid added to pyrogallie in the developer as recommended by M. Claude,

is quite as powerful as the ordinary iron developer, and moreover that the nitrate both does not require to be added, the quantity of nitric acid usually referred to be added. The day on which I made these comparative experiments was one very miserable for successful photography, the light being dull, and the sky covered with dark masses of clouds. The lens I used was the front one of a French half-plate portrait combination reversed, forming a 14-inch view lens, the stop I used being 2 inch. The bath was an old one that had been neutralized and covered the day before; on mixing I added 7 drops of a dilute solution of nitric acid (1 part acid to 7 water) to each pint which, therefore, contained 7 drops of pure acid. The collodion I used was rather a complicated composition, and is one that I generally employ for photographing anatomical preparations, &c. It is composed of equal parts of Mawson's collodion for iron development, Rank's bromo-iodized and some of my own made, iodized after E. Glaisher's formula for iron-uranous collodion. You will see by the above that my collodion contains a considerable proportion of bromid salts.

Having coated and sensitized a plate I exposed it for fifteen seconds with the above-mentioned stop and lens. On applying the formic acid developer, an image started out with marvellous rapidity. On inspection, the negative proved to be under-exposed. I prepared another plate, and gave it seven more seconds. The result was a fine, clear well-defined negative with deep shadows; perhaps if anything, very slightly over-exposed. I enclose a print from it for you to judge from. The developer I made as follows:—

Pyrogallie acid	20 grains
Formic acid	4 drachms
Alcohol	4 "
Water	10 ounces.

Dissolve.

The formic acid I obtained from a chemist in Southampton (Mr. Downman).

I next prepared a plate with the same collodion and bath, and exposed it precisely the same time, but developed with—

Sulphate of iron	20 grains
Acetic acid	15 drachms
Alcohol	15 "
Water	1 ounce.

The result was a negative full of detail, but far surpassed with the preceding one. I enclose a print for you to compare with the other one. I think from these experiments you will agree with me that formic acid is an accelerator, and that to a considerable degree as a plate prepared with bromo-iodized collodion, and developed with the old pyrogallie acid and acetic acid developer, would have required at least three times the exposure as when developed with iron.

I intend, during the ensuing week, instituting a series of experiments to prove whether the formic acid developer will prove successful with plain iodized collodion, and other conditions of bath; also in combination with iron.

I enclose a print from a tennis and tennis negative of the main wing and centre block of the Royal Victoria Hospital. The building forms a rather bad subject to photograph, being built of unexcelsior red bricks and white limestone. I had Mawson's collodion for iron development, with the addition of 1 grain of bromide of cadmium to each ounce, make a capital collodion for this process.

Hoping you will excuse me for consuming so much of your valuable time, I have the honour to be, Sir, your most obedient servant.

W. A. Moss, Sergeant Army Hospital Corps.

Royal Victoria Hospital, Netley, September 10, 1863.

[The prints enclosed by our correspondent are very good, and fully bear out his position.—P.]

Photographic Notes and Queries.

IMAGE ON THE RETINA OF A DEAD EYE.

DEAR SIR,—Seeing in our local paper the other day an account of a peculiar photographic incident stated of having been going round of the French papers, I found it to be Mr. W. A. Warner's experiment of photographing the eye of a calf shortly after death, reproducing on the photographic plate a representation of the pavement, &c., of the slaughter house. I remember a brief account of this appearing in the News a considerable time ago.

My object in writing is to ask Mr. Warner (who by the bye is always willing to give his brother photographers the benefit of his experience), to give a few further particulars respecting this very singular phenomenon, and also if he has made any further experiments, as I am sure it will be a subject of interest to photography.—I am, sir, yours truly,

ENQUIRER.

Leeds, September 2, 1863.

[We know nothing personally on this subject beyond the reports often alluded to; possibly Mr. Warner may have further evidence on the subject. We have been generally disposed to regard such stories in the light of *canards*; but whilst we never receive things as truths except on satisfactory evidence, we do not reject well authenticated statements as falsehoods, simply because they appear improbable. Many things appear improbable simply because they belong to a range of facts which have not come within common experience.—ED.]

Talk in the Studio.

PHOTOGENIC PROPERTIES OF THALLIUM.—Mr. Crookes, in his recent paper before the British Association, remarks:—Several thallium salts are sensitive to light. The protochloride and double phosphate of thallium and ammonia are especially so.

LIME TONING.—Our correspondent, "A Photographer's Assistant," has recently sent us prints from various batches of paper, some of which were very prone to mealiness. All the prints are very brilliant, of a rich, warm, black tint, and quite free from mealiness. They are all toned by modifications of the lime bath, made to suit the existing conditions.

PHOTOGRAPHS IN PRINTING INK.—Mr. Pouncy informs us that he finds mineral naphtha, which is less than half the present price of turpentine, may be used in place of the latter in developing or removing the superfluous pigment from his prints. We had already tried it and found it to answer; but with one slight drawback. When naphtha is used the print is rapidly cleared, but the black pigment is apt to be precipitated in a powdery form, some of the particles clinging with obstinacy to the whites of the picture. With care or further practice this difficulty would probably be got over. Mr. Sutton has just issued a pamphlet on the subject which we hope to review in our next.

To Correspondents.

T. C. F.—The reply to one of your questions was omitted in our last. There is no difficulty in becoming a member of the Photographic Society. You require to be proposed by a member; we will have pleasure in doing this for you. The subscription is a guinea a year, and a guinea entrance fee. Any further particulars you can learn of the Secretary, Dr. Diamond, Twickenham House, Twickenham.

WALTER H. DAVIES.—The most fully detailed description of the process of photolithography was that of Mr. Osborne, given in our pages twelve months ago. In the process of M. Morvan, regarding which you inquire, the proportions are as follows:—Albumein 6 parts, water 6 parts, bichromate of ammonia 1 part; apply with a soft brush. A transparent positive on glass must be used, as it is the parts which have been protected from light which form the blacks of the subsequent picture. After the stone has been treated with soap, an ordinary lithographic roller and ink are used, we presume.

HOW.—We have not any exact information regarding the existing Architectural Photographic Association. The old one was dissolved some time ago. We have seen recent allusions to the existence of another, but no notice of its origin or character. We believe it is in some way connected with the Architectural Association, and has its local habitation in Conduit Street, Regent Street. 2. We cannot explain the cause of the spot referred to without knowing further particulars. We have seen such spots arise from various causes, and it may possibly be a defect in the paper. It is impossible to form a very definite idea of the quality of a portrait which has the greater portion of the face carefully cut away; but it seems to be pretty good. 3. The print of Lacock Abbey, from a wax-paper negative, is too deeply printed; but is otherwise satisfactory. 4. A pale over-donc

tannin negative may be intensified by various methods. Perhaps the most suitable is as follows:—Make a solution of 1 grain of iodine and 2 grains of iodide of potassium in 1 ounce of water. Apply this to the plate for a few minutes, in daylight, and wash. Then take a 3-grain pyrogallie acid solution with 2 grains of citric acid, and add a little of a fresh silver solution. This will readily give you intensity.

11. FAONSHAM.—The double sulphate of iron and ammonia is of a very pale green tint. It keeps in crystals perfectly, and pretty well in solution. 2. An iron developer which has been long kept loses some of its energy, and develops slowly but with great clearness. Sometimes, when very old, it requires the plate to have been longer exposed than a fresh solution. 3. An iron solution with its proper proportion of acetic acid, kept in a well stoppered bottle, will keep for months without much injury. We cannot tell you how long sweetwort will keep; but it is a very unstable preparation and would probably rapidly change, especially in warm weather. 4. The use of a chloride of calcium box is to keep excited paper from discolouring when prepared some weeks beforehand. The chloride of calcium effects this by keeping the atmosphere in the box very dry in virtue of its own affinity for moisture. 5. We have seen some prints produced by development which could not be surpassed for beauty; but they generally lack the brilliancy and transparency of prints obtained direct. 6. The numbers of the PHOTOGRAPHIC NEWS for one year form a volume. If you send direct to us we will endeavour to get you an ALMASAC.

NO SIGNATURE.—A correspondent who does not append a signature to his letter, but encloses two cards. Are the spots regarding which you inquire in the negative or only in the prints? At present we do not see the cause.

1. The chief fault in the unmounted prints is over-exposure of the negative. Give your negatives less exposure, and use more direct light and less diffused light. 2. Two ounces of hyposulphite of soda will fix from a hundred to a hundred and fifty card pictures, but it is wise to keep within the number. The time of immersion will vary from ten minutes to twenty minutes, depending on the thickness of the paper and on temperature. 3. A bath neutralized with ammonia is apt to get out of order and cause fog, as solution of nitrate of ammonia will hold oxide of silver in solution. With care you may, however, use the solution either as a negative or positive bath. 4. If the prints are kept in motion, and the water frequently changed or kept running, about six hours, are sufficient for washing. Some persons prefer to give twice that time. 5. The address of Messrs. Hopkin and Williams is New Cavendish Street.

THE UNKNOWN asks us if there be anything in photography to influence the minds of its votaries for evil. He says, "I know scores of photographers, all of whom have shocking tempers, are frightfully proud, and seem to think none such good artists as themselves." He also sends us some lines which he thinks especially suitable for the perusal of photographers generally. We really cannot agree with him. Photography is an art which, especially when practised professionally, makes great demands upon the patience of its students, and often tries the temper in various ways. Notwithstanding this, we believe it numbers amongst its disciples some of the best fellows in the world—men patient and unwearied in the pursuit of excellence in their all-absorbing art, and genial and estimable in social life. A cantankerous photographer is an exception to the general character.

AN AMATEUR SUBSCRIBER.—We do not quite understand what you mean by both negatives and positives turning yellow when they are varnished. The pure whites of glass positives are often degraded a little by varnishing, especially if you use a strong-bodied spirit varnish. The use of "Newman's Colouring Varnish," or the "Alabastrine Varnish," sold by Squire, will obviate this. The nature of the injury to the negatives produced by varnishing, we do not quite understand.

R. G.—Collodion which has acquired colour from age is favourable to intensity. When the colour is communicated by adding free iodide, the only way in which intensity is effected is by the plate permitting longer development without fogging, and thus getting more intensity. Otherwise free iodide does not, *per se*, affect intensity. Nor does it with a bromo-iodized collodion cause insensitiveness. Its chief use is to aid in preserving clean shadows.

HYPO TONING.—Some samples of paper are very prone to lose much of their tone in the hypo bath; in which case it is desirable to tone much deeper than is required and tone slowly. Nevertheless, the tone of the print you enclose is in our estimation very pleasant. We prefer warm tones for landscapes and similar subjects.

AN AMATEUR.—Remove the lens from its cell and blacken the edges; that will probably remove the spot of light, which probably proceeds from reflection. 2. Mawson's collodion is bromo-iodized.

M. A.—The examples of your sensitive film reached us so broken and abraded that we could not make a satisfactory examination. We have not met with anything of the kind, nor can we account for it. Is your tannin solution carefully filtered? And are your plates sufficiently washed? We will give the matter some further attention.

T. W. T.—We will forward the question to Colonel Stuart Wortley, direct. BROWN STAIN.—A correspondent, whose letter is at this moment mislaid, asks the cause of the brownish yellow stain in the face of an old lady. It appears to be the result of under-fixation, the hypo bath probably being old, and the print not well immersed, or, perhaps, stuck to another.

MA. WARNEA, of Ross, begs us to state that he is in receipt of a 5 by 4 negative, "A Gentleman sitting by a table," without any directions as to what is to be done with it. Any gentleman having forwarded the same will oblige by writing him thereon.

Several Correspondents in our next.

NEW AND SIMPLE METHOD OF GOLD TONING.

WE have recently been experimenting with a method of toning which possesses the merit of great simplicity, and does not require the solution to be prepared some time in advance. The prints, after being well washed, are immersed for five minutes in a solution containing from five to ten grains of carbonate of soda in an ounce of water. They are then carefully drained, and without further washing immersed in a solution of chloride of gold, one grain in about five ounces of water, without any other addition. The prints retain sufficient of the alkaline solution to preserve them from the action of any trace of free acid, and also to set up the necessary decomposition to produce toning action. The toning also seems to proceed very gradually, and without the slightest tendency to mealiness, or to any excessive bleaching.

We are so well satisfied with the acetate bath for warm tones, and with the lime bath for black tones, that we do not bring this forward with any view to supersede these methods; but as a simple and convenient method of proceeding, either when mealiness is troublesome, or when a bath requiring time for its preparation is not ready.

HISTORY OF CARBON PRINTING.*

MR. SUTTON has written an interesting little work on Mr. Pouncy's process of producing photographs in printing ink, in which he glances at the history of carbon printing generally, and more especially of what he terms direct carbon processes, or those methods by which a print is produced on paper prepared with carbon, combined with some sensitive material, of which Mr. Pouncy's patent process is the latest and most perfect example.

The work is written with that simplicity and vigour of style with which Mr. Sutton's readers are familiar; but there is also something of the tone of the advocate who knows no other excellence than that the cause of which he is pleading. For instance, in the Introduction to his work, the importance of a carbon process is enforced by an allusion to the instability of photographs produced by other methods. The instability of photographs has been an admitted reproach, but not the implied universality of that instability. Mr. Sutton says:

It is the reproach of all photographs produced by the common methods that they fade. Beautiful as they are in colour and effect, want of permanency is the unfortunate stigma which attaches to them; and if the term permanent is ever applied to any class of common photographs in contradistinction to another, the term must be understood as employed in a very limited and relative sense, for no one has a right to affirm with confidence that either a silver print, a Daguerreotype, or collodion positive or negative, however carefully manipulated or preserved, will absolutely remain unchanged during even the short space of a

dozen years. Some processes may yield proofs less liable to change than others, but none of those which are commonly employed by photographers yield results which are at all comparable in permanency to the works of the painter or engraver. Had pictures and prints been as perishable as photographs, what would have become of the arts of painting and engraving? Or had impressions pulled in the printing press been as liable to fade as photographic positive prints, where would civilization have been at this moment?

Now, if we are not mistaken, Mr. Sutton has frequently reiterated that he has never known a developed print to fade. In a recent conversation with Dr. Diamond, on calotype negatives, he stated that he had never known one to fade, and we need scarcely add that there is no higher authority on that subject. We have never known a well kept collodion negative, collodion positive, or daguerreotype to fade. Indeed, we have never known a daguerreotype which had been properly gilded to fade at all. By exposure to damp or foul air, we have known them to become tarnished, &c., but we have never met with one of which we could not, in a few minutes, restore the pristine beauty, by the simple application of a solution of cyanide of potassium, and we should feel no hesitation whatever in affirming, with all confidence, that a carefully produced and fairly protected daguerreotype or collodion positive would remain unchanged very much longer than a dozen years. It is upon ordinary prints on paper that the chief stigma has rested. These, if produced with proper care and observance of all known conditions, will, we doubt not, remain unchanged for more than a dozen years; but, nevertheless, it is an unfortunate fact that owing to the combined effects of ignorance and carelessness in the past, few persons would like to stake their reputation on the affirmation that any given print would remain unchanged for, perhaps, half of a dozen years.

Hence the unquestionable importance of a carbon printing process as a means of giving to photographs absolute and unquestionable permanency. "But," as Mr. Sutton pertinently remarks, "at the same time it must be granted that unless this problem can be solved in such a way as to sacrifice none of the beauty of the common photographs it will be comparatively valueless, because permanency will never be considered an equivalent for the absence of beauty and other good qualities." Mr. Pouncy's process is a very great advance in this direction, and we believe, when well worked, will prove still more so. At present we cannot say that we have seen such perfect prints produced by it as we have seen by M. Fargier. But whilst the process of the latter gentleman is, we believe, so beset with difficulties that it is very unlikely to become a practicable commercial process, Mr. Pouncy's is elegant and simple, and promises, in skilled hands, to give better results than have yet been produced by any carbon process.

Mr. Sutton emphasizes the idea which we suggested in our article on the subject in the PHOTOGRAPHIC NEWS for July 31st, which contained the first published description of

* "Photography in Printing Ink." By Thomas Sutton, B.A. London: Sampson Low, Son, and Co.

the process in detail. We then suggested that the obtaining of half-tone was probably due to the action of light reaching that portion of the sensitive compound which was in contact with the paper first, the principle being similar to that upon which M. Fargier obtained half-tone in his carbon prints. Mr. Sutton says:—

The principle of getting half-tone consists in printing *through* the paper, because then none of the material which is acted on by light is subsequently washed off, and the intensity of blackness will depend upon the exact power of the negative to stop the light in its different parts. The paper is so thin, and its surface so fine, that printing through it does not injure the definition. And lastly, the black stuff is so perfectly soluble in turpentine, where the light has *not* acted, that the *whole* of it is dissolved from those parts, leaving them as pure and stainless as if nothing had been applied to the paper.

We ascertain further from the pamphlet before us a fact which had previously escaped attention, namely, that this suggestion for the production of half-tone was not originally due to M. Fargier, but to one of our own countrymen, Mr. Blair, of Perth. M. Fargier's process was patented in the latter part of 1860, whilst Mr. Blair's letter, containing the suggestion, was published in the *Photographic Notes*, in January, 1859. As we conceive this to be a very important point in the improvement of carbon printing, we think it important to give to Mr. Blair the definite recognition of his original suggestion.

We now extract Mr. Sutton's brief *résumé* of the history of carbon printing.

Before proceeding to the history of carbon printing it is necessary to define clearly what is included by the term, because, unless a precise definition is now given, it might be supposed to include processes of a different nature, but which lead to a somewhat similar result, when it is only required to obtain copies in which the dark parts consist of lines or dots.

By carbon printing, in its strict sense, is meant the art of obtaining a positive photographic copy from a negative, at one operation, by the direct action of light, the carbon being mixed with the sensitive material that is applied to the paper, and then fixed to the paper by the action of light. There are other processes in which an image is first obtained upon a photographic tablet by the action of light upon some chemical substance which does not contain the carbon, and the carbon is afterwards applied to the image and made to adhere to the dark parts of it; but those processes must not be confounded with that which is more strictly defined as carbon printing, and which is the only one that will at present render half-tone. To prevent confusion, the latter might be called direct carbon printing, and the former applied carbon printing. The various photolithographic processes, and probably also the prototype of M. Joubert, come under the latter denomination, and no allusion need be made to them in this work, because they are based upon a different principle from that which is described here, and will only yield successful impressions in lines, or dots, and not in half-tone.

Having thus defined carbon printing, the history of that art will evidently not include any account of the labours of those who have employed solely the applied processes, for purposes of obtaining copies of objects in lines or dots. We are simply concerned now with the history of an art by which it has been found possible to reproduce successfully in carbon all the delicate gradations of tone which exist in a good negative photograph.

Of course the art of carbon printing includes the process of printing on the same principle in various coloured pigments, since these merely take the place of carbon in the operation.

The first suggestion of the idea of employing colouring matter in a state of mixture with a sensitive substance, in order to get a coloured positive impression by exposure to light, is due to Mr. Mungo Ponton. That gentleman, in the year 1838, published in the *Edinburgh New Philosophical Journal* the account of a process by which he prepared sensitive positive paper with a mixture of bichromate of potass (the sensitive substance), and sulphate of indigo (the colouring matter), and thus obtained a print in which the lights and shadows exhibit different shades of green.

In the above process, it will be observed that the colouring matter, sulphate of indigo, is not strictly a pigment but a coloured solution.

The next step was not taken until many years afterwards. In 1855, M. Alphonse Louis Poitevin took out a patent in England, bearing date December 13th, in which he vaguely describes a process by which a direct carbon print may be obtained.

The following is an extract from that part of his specification which bears upon this subject:—

I apply various liquids and solid colours upon paper, cloth, glass, and other surfaces, by mixing such colours with a mixture composed of equal parts of a concentrated solution of albumen, fibrine, gum arabic, gelatine, or similar organic substance, and a concentrated solution of bichromate of potass, or of any base which does not precipitate the organic matter of the first solution, and applying this new mixture or combination to the paper, or other fabric or surface.

The photographic impression is produced upon this prepared surface by the action of light passing through a negative photographic picture, or an engraving, or other suitable object, or screen, or in the camera obscura, and it is then washed with a sponge and a large quantity of water. The albumen, or other organic matter, is rendered insoluble at the parts where it has been acted on by the light, and the design is thus produced in the colour which has been employed. Mixtures containing different colours may be applied to different parts of the surface corresponding to different parts of the negative or screen employed to produce the photographic impression. A design in several colours may thus be produced. The proportions of the materials may be varied.

What I claim as new is, the mode of printing upon paper, cloth, glass, or other suitable surfaces, by applying to them a mixture of liquid or solid colours, with the aforesaid chromatised albumen or other organic matter, and exposing to light as hereinbefore mentioned, and afterwards washing away those portions of the mixture which have not been acted upon by the light, as hereinbefore described.

There can be no doubt that the above patent contains the idea of a process of direct carbon-printing; but there is no evidence to show that M. Poitevin ever produced a carbon print by the process described until some years afterwards, when Mr. Pouncy, of Dorchester, had done so, and given an exact formula. It is notorious that a large proportion of the patents granted in this country are for mere ideas, and there is no evidence to show that M. Poitevin's process was anything more than an idea. He never publicly exhibited a carbon print taken by himself prior to the publication of Mr. Pouncy's exact formula, although repeatedly challenged to do so. The idea which he patented was evidently based upon Mr. Mungo Ponton's process, and is but a very slight extension of it. It is needless, however, to say more on the subject, because M. Poitevin's method has now been superseded by one infinitely better, and his patent was allowed to lapse.

The next in the field was M. Testud de Beauregard. He took out a patent in England, bearing date December 12th, 1857, for an invention which consists in producing photographic proofs or pictures by means of carbon or other colouring matter, applied by superposition, to a coating sensitive to the action of light. The following are the particulars gathered from his specification:—

Paper is immersed in or floated upon a warm solution of bichromate of potass or ammonia, mixed with gelatine. It is then dried, and its surface covered with the pigment. The pigment may be rubbed over the dry surface with a pad of leather or other suitable material, or it may be ground very fine with nut oil or other oil, and rubbed over the surface, which is subsequently immersed in a bath of ether, to which a little collodion may be added, or the paper may be immersed in a bath of indian ink, or other pigment, ground up very fine with water and mixed with gelatine, and a little gum or dextrine, and used hot; or rollers, or presses, or other apparatus may be employed to apply the pigment or assist the operation. The paper having been prepared in the dark, is exposed to the action of light and washed in hot water. This dissolves the gelatine which has not been acted on by the light, but does not dissolve that which has been rendered insoluble by the action of light, and which insoluble gelatine retains the pigment, and thus produces the image. Glass or other substances may be substituted for paper. By employing carbon, pigment, or finely-divided gold or silver, photographs or pictures of the greatest permanence and durability may be obtained.

As in the case of M. Poitevin, there is no evidence to show that M. Beauregard ever publicly exhibited a carbon print taken by the above process prior to the publication of Mr. Pouncy's method a few months afterwards.

The history now takes us to the part which I have myself played in this matter. Without knowing anything of what M. Poitevin or M. Beauregard had patented, I published the following leader in my *Photographic Notes* of January 1st, 1858:—

Some experiments in which we were engaged a few weeks ago, lead us to believe in the possibility of printing in carbon, by the following process:—

First.—Dip a sheet of blotting-paper in a mixture of bichromate of potass, albumen, and finely-ground charcoal, or blaken it (in the dark), with indian ink, ground up with a solution of bichromate and gelatine, or albumen.

Next.—Dry the blackened paper, and expose it to light under a negative.

Lastly.—Immerse it in water, which will more or less perfectly remove the black material from those parts where light has *not* acted without disturbing those parts where light has acted, and thereby rendered it insoluble

In this way, a print in black, and a sort of dirty white, may be produced; after which it is probable that immersion in an alkaline solution may clear up the lights sufficiently. This was the direction in which we were experimenting a few weeks ago, when some matters interfered to prevent our carrying the experiments any further.

About two months after the publication of the above article, I received by post, from one of the subscribers to the *Notes*, Mr. John Pouncy, of Dorchester, several prints, which he assured me were veritably printed in carbon, by the direct action of light upon the paper. These prints were clean in the lights and very promising in general effect, although the process was then far from perfect.

Mr. Sutton then proceeds to narrate the details of Mr. Pouncy's first carbon process, of its publication, and the sum of £80 presented to Mr. Pouncy by subscription. He then adds:—

The publication of Mr. Pouncy's process made a great stir among photographers both in France and England; but although it was tried and abandoned by most persons as incomplete, still the possibility of producing a carbon print in this way having been practically demonstrated, several enterprising and intelligent experimentors took it up as the basis of various modifications which have since been largely applied to useful purposes. The names of Asser, Salmon, and Garnier, Joubert, Sir Henry James, Mr. Osborne, M. Fargier, and some others will be familiar to most readers of this work, as the inventors of various modified processes in which carbon forms the material of the photographic reproduction.

We may remark, before proceeding further, that Mr. Sutton omits, in the *résumé* we have quoted, to mention the name of M. Becquerel, who, in 1840, experimented largely with the combinations of bichromates and organic matter. Nor does he do entire justice, we conceive, to M. Poitevin and M. Beauregard, in both of whose processes the elements of carbon processes are very distinctly enounced; whether either of them did or did not ever produce pictures by these processes, we are not in a position to state. But still more unfair than this is it, we conceive, to refer to the processes of Joubert, Asser, Osborne, James, and others, as modifications of Mr. Pouncy's process, seeing that they bear no more relation to it than they do to Poitevin's, propounded years before. M. Poitevin's specification did, indeed, include a system of photolithography, and whether it ever were reduced to practice or not, his was undoubtedly the first published germ of the application of Mungo Ponton's discovery to photolithography. Other experimentalists, amongst whom we may mention our present contributor, Mr. Joseph Lewis, had been working in a similar direction but had not published. The independent discoveries of Asser, Osborne and James respectively of the transfer process, constitute a definite and distinct landmark in the history of this branch of photography. These gentlemen had each profited, doubtless, by the labours and discoveries of those who had preceded them, of Ponton, Becquerel, Talbot, Poitevin, and, possibly, of Mr. Pouncy; but it appears to us as unfair to describe the processes of these gentlemen as merely modifications of Mr. Pouncy's process as it would be to describe his as simply an imitation of M. Poitevin's.

Let us be distinctly understood. We do not wish to deprive Mr. Pouncy of a title of his just reward or credit. We have, very ungrudgingly, and we think heartily, acknowledged the merit of his latest process. We have accorded to him the credit of a hard-working, persevering, and ingenious experimentalist. We did not begrudge him one farthing of the £80 by which his first labours were acknowledged. We hope he will receive still more substantial reward for his more recent efforts. But we deprecate, on his own behalf, as well as on behalf of other photographic inventors and the photographic public at large, undue and over-comprehensive claims on his own behalf, because such claims produce a recoil in the public mind, which will prevent him receiving the full justice which would otherwise be readily accorded. Mr. Sutton is a warm, generous, and enthusiastic advocate, who is, by his enthusiasm, led

to make claims which cannot, we think, be supported, and are scarcely judicious.

The question of Mr. Pouncy's treatment by the Photographic Society is freely handled in the pamphlet, and in a tone far from complimentary to the society. We do not care to discuss the matter now, beyond remarking that a body of men acting without premeditation or concert, rarely do intentional injustice; and that, if Mr. Pouncy received less than justice from the society, an injudicious mode of introducing his discovery was in some degree chargeable for the reception it met.

The perfection of all processes in photography has been attained by slight steps, and the contributed suggestions of many persons. This is not less true of carbon processes and photolithographic processes than of other branches. Nevertheless, Mr. Pouncy's is a distinct advance, not less the result of a happy ingenuity than of careful experiment. Mr. Sutton refers the first use of asphaltum to Nicéphore Niepce, and reminds his readers that he (Mr. Sutton) was the first to experiment and publish results with the use of a greasy ink, results which probably suggested the transfer processes of Asser, Osborne and James. He adds:

But no one, to the best of my knowledge, had ever used a mixture of asphaltum and printer's ink as a sensitive coating applied to paper, before Mr. Pouncy employed it in that way, and to him is due the whole merit of utilizing this mixture in the manner described in his patent. In this respect he has proved that he is something more than the mere industrious worker out of other men's ideas; and that he is truly an inventor and pioneer, as ingenious in resources as he is indefatigable in experiment.

We believe Mr. Sutton is right, although it is quite possible that we shall learn ere long that asphaltum played a part in the pictures of Watt, or Bolton, or Wedgwood. The nearest approximation to Mr. Pouncy's mixture is to be found in Mr. Gibbon's process described before the Glasgow Society on the 7th of last January, by Mr. Mactear. In this method, copal varnish, linseed oil, Brunswick black, mastic varnish, and turpentine,—all elements of printing or transfer ink—are combined with bicarbonate of potash. This mixture is, however, for application to a lithographic stone, and not to paper for producing a proof direct from a negative, as in Mr. Pouncy's ingenious process.

Mr. Sutton, in describing the process, practically ignores the use of bichromate of potash, using asphaltum as the sensitive agent, remarking in another place that it is doubtful whether the addition of the former is attended with an good effect. Mr. Pouncy expressed his regret to us that its insolubility prevented him from adding a larger proportion than he did, as the paper would be much more sensitive if more could be added. We then suggested, as a method of adding more, that it should be dissolved in a very small quantity of water, and by the aid of an alkali combined with the greasy ink. Since then we have tried the experiment, and have thus combined bichromate of potash with ordinary printers' ink, which, on being applied to albumenized paper and exposed to light, become insoluble in turpentine, just the condition required. Other engagements have prevented us from following out the experiment to further practical results. But we mention the fact for the benefit of other experimentalists.

We have already occupied more space than we intended but we shall probably, on another occasion, make another extract from this interesting pamphlet.

JOTTINGS FROM THE NOTE-BOOK OF A "PHOTOGRAPHER'S ASSISTANT."

No. I.—THE IMPORTANCE OF PHOTOGRAPHY.

NOTWITHSTANDING the many and continued efforts put forth by photographers, in order that the capabilities of their art may be fully developed, the vast improvements which

have already been effected, the rapid pace at which it still advances, and the popularity it has attained, in spite of all these advantages, its recognised position remains anything but satisfactory; like the illustrious Pickwick when he lighted unwittingly among the sage provincial politicians, it is regarded with the green eye of suspicion, whichever side it turns for sympathy; science will not acknowledge it, and art repudiates its claims to kindredship with an air as scornful as the purse-proud squire would refuse the proffered hand of a poor relation. The absence of its representative in that brilliant array of intellect recently assembled in the north, proves that the stars of science are unwilling to give it a place, even as an humble satellite in their too exclusive system. Again, those suns of art, at whose magic touch forms of life and beauty spring into existence pure and bright as angels' smiles, glowing in all the richness of nature's colouring, the bosom of the once despised canvas at their command becomes an object of intense interest, and crowds rush on to do homage before the shrine of that genius, who obstinately refuse one ray of warmth yielding encouragement to their less aspiring, though no less deserving, handmaid.

In seeking out the root of these prejudices, we find that, like the shrine-makers of Ephesus, the acknowledged luminaries of science and art consider the progress of photography endangers their craft. We admit willingly that the *influence of scientific pedantry is endangered, whilst that of the genuine son of art or science is largely increased.* There exist scientific pretenders who have long enjoyed a privileged existence, separated from the common masses by a broad line of demarcation. They have fortified their position with an outpost of mysterious technology; weak points have been guarded with hard-sounding words, to sear ordinary minds from an attempt to scale their interpretation, and to render their position more impregnable, huge embankments of unintelligible theories have been raised, and here those philosophers take their stand: armed to the teeth with logic, they defy the lilliputian world before them, and any attempt to enroach on their ground is speedily met by a crushing volley of wordy projectiles.

Photography is destined to break through these formidable impediments. Based on principles that form the very groundwork of natural philosophy, it is silently cutting a trench through which ordinary mortals may travel free from any risk of stumbling over a memory-splitting nomenclature. Taking photographic art as a basis for scientific inquiry, the task is converted into pleasure. Take, as an illustration, optical science with its mysterious array of sines, angles, and dotted arrows: viewed with a photographic eye, these become fascinating. Invisible rays of light bear on their wings living pictures; the lens, like the human eye it so beautifully imitates, collects and arranges each ray as it comes under its refractive influence. Chemistry now steps in, at whose word those fairy-like scenes assume a new existence and start into a new being as a vivid and truthful reality. Works of art, curiosities of nature, fossils that speak of ages long gone by, when monsters wandered unmolested o'er a sinless world; wondrous monuments of art raised by the industry of men whose natural bodies have long since mouldered into dust; the living forms of a still existing race, from the aborigines of comparatively unexplored regions to the high and mighty ones of a civilized world; the monarch on the throne; the inmates of the humble cottage; old age and infancy; all these forms has the lens filtered from surrounding light, and chemistry has set its lasting seal on the otherwise fleeting picture, thus giving existence to a promoter of tastes that will assuredly bear fruits glorious to contemplate. Our art has awakened curiosity, its practice is not confined to rank or station, its followers may be numbered by thousands, each more or less study its leading principles; these embrace the rudiments of scientific research; a desire for increased knowledge is excited and the world will grow the wiser and better for the change. Fain would we enlarge widely on this sense-

enthraling theme, but space bids us close a jotting intended to awaken an interest in the minds of photographers to remarks of a practical nature that will form the subject of future jottings. As "printing difficulties" is the all but universal cry, printing difficulties, for a time, we select for a theme, and as far as our ability permits, will endeavour to prove that printing troubles will vanish when touched with the magic rod of a well grounded and thoroughly understood system.

PHOTOGRAPHIC CHEMICALS:

THEIR MANUFACTURE, ADULTERATION, AND ANALYSIS.

THE other compounds of arsenic, together with those of antimony, tellurium, and bismuth, are of too little interest to the photographer, to require mentioning in these chapters. The metal zinc next claims our attention. This is very largely used in laboratories for the preparation of hydrogen gas. For many purposes commercial zinc answers sufficiently well for the preparation of this gas: it should be granulated in the following way:—The metal is melted in an earthen crucible, a little powdered charcoal being put on the top to hinder the oxidation somewhat. When melted, stir with an iron rod, but do not let the temperature rise much above the melting point. Have ready a pail nearly full of water; scrape off the charcoal and scum from the surface of the metal with an iron spoon, and then grasp the crucible with a pair of tongs, hold it about three feet above the surface of the water, and pour the metal into it in a thin stream. The melted metal will, of course, produce considerable noise on contact with the water, but no danger need be apprehended. The zinc will now be seen to form a bulky conical pyramid in the pail; it must be transferred to a cloth and quickly dried in a warm place. This process of granulating yields the metal in a state peculiarly adapted for the preparation of hydrogen gas, as it is divided into small pieces, exposing a considerable surface for the action of acids. Zinc is liable to contain a great many impurities, varying considerably with the source whence the metal is obtained. Manganese, arsenic, antimony, cadmium, tin, lead, iron, cobalt, nickel, and copper, are all liable to be present. Most of these can be separated by distillation; but unfortunately, the arsenic and antimony, which are by far the most important impurities, cannot be got rid of in this manner.

According to Maillet, the arsenic may be removed by fusing commercial zinc and granulating it as above described, but at a high temperature, so as to get it in as fine a state of division as possible. Four parts of this granulated zinc, together with one part of nitre, are then placed in a crucible in such a manner that there may be a small portion of free nitre both at top and bottom, and the whole is heated in the furnace till vivid combustion ensues. The crucible is then taken out, the slag removed, and the zinc either poured into water or into a mould. The absence of arsenic may be ascertained by dissolving some of the zinc in pure dilute sulphuric acid, and allowing the evolved gas to pass along a German glass tube, one portion of which is kept at a red heat. If arsenic be present, a dark coloured ring of this metal will be gradually formed round the tube where the heat has been applied. If no deposit takes place after half an hour, the zinc may be considered free from arsenic. It may frequently happen that arsenic will be found in this manner, when pure zinc is used, as sulphuric acid almost always contains a certain quantity of this body. It will, of course, be necessary to have the acid free from arsenic before a trustworthy test can be applied to the zinc. A method of obtaining sulphuric acid sufficiently pure will be given subsequently.

Besides its use in preparing hydrogen, zinc is largely consumed in galvanic batteries. Pure zinc is not necessary for this latter purpose, as the process of amalgamation which battery zincs always undergo, renders the ordinary impurities of no moment. The effect of amalgamation is very curious.

An amalgamated zinc plate put into dilute sulphuric acid is violently attacked, torrents of hydrogen being evolved; if a drop of mercury is poured on to it, the evolution of gas ceases instantly, and the amalgamated metal now behaves towards the acid as though it were absolutely pure: pure zinc being very difficultly soluble in sulphuric acid. For galvanic purposes, zinc should always be well amalgamated, as local action, that is, solution of the zinc when the battery is not at work, is avoided. When the zinc plates of the battery are not in use they should always be kept in dilute sulphuric acid, about one part of acid to thirty or forty of water; by this means the surface is always kept bright and ready for use. The loss by solution is scarcely appreciable, and when the battery is wanted the tedious operation of cleaning and re-amalgamating the zinc is avoided. Should they ever require reamalgamation, it is only necessary to place a drop of mercury on the centre of each plate, and it will run over without further trouble.

Zinc is a very crystalline metal. At the ordinary temperature it is very hard and difficult to bend. At a little above the boiling point of water, however, it is very ductile and malleable, and may be readily bent into any desired shape. If the temperature be raised a little higher it becomes brittle again, and at 205° C. it is so brittle that it may be pounded in a mortar. Zinc fuses below redness, but above the melting point of lead; at a white heat it boils, and may be readily distilled. It is tolerably permanent in the air, becoming coated with a thin grey film, which prevents further oxidation. In moist air, in the presence of carbonic acid, a white tarnish forms on it. When zinc is heated to redness in the air it burns with a dazzling bluish and greenish flame, and forms oxide of zinc, which floats about the room and falls down in large flakes like wool. In this form oxide of zinc is an excessively light powder, but, by appropriate means, the oxide can be prepared in a much denser form, and in that state is largely used as a pigment, under the name of zinc white. It has the great advantage over white lead, that it is not darkened by sulphuretted hydrogen, the sulphide of zinc being white. When first introduced, zinc white was not liked on account of its not having so much body as white lead, but it is gradually gaining ground by reason of its other valuable properties. For miniature painting it should always be employed in preference to white lead.

We have met with some samples of zinc white containing a large amount of impurity, sufficient, indeed, to cause it to darken when exposed to the action of sulphuretted hydrogen. This impure zinc white is generally seen to have a less brilliant colour than the best quality, and it is at once darkened upon the addition of a little dilute sulphide of ammonium or sulphuretted hydrogen water. This test should always be applied by artists.

PHOTOLITHOGRAPHY.

No. III.

BY JOSEPH LEWIS.

VARIOUS METHODS OF OBTAINING A PRINTING SURFACE.

From the rapid multiplication of the methods introduced, it becomes advisable to attempt a classification of the various processes contrived to produce a printing surface for the press by the actinic influence of light, without regard to the nature of the original, whether it be itself a photograph or otherwise produced, according to the following order or class:—

- 1st. The sensitive salts of silver.
- 2nd. The sensitive resins, oils, and bitumen.
- 3rd. The chromic salts and organic media.
- 4th. Some of the above in combination.

This classification embraces the various methods of producing a photo-printing surface by means of the lithographic

principle, which is based on the fact that water is repelled by grease, and *vice versa*.

The processes hereinafter described, and also that in my second article, at page 214, come immediately under the first division. An inked surface is made the foundation for the sensitive film.

2. An unvarnished negative (collodion) is treated in same manner as for transferring positives to leather, by detaching the film by acid and alcohol, and a card being already coated with sticky transfer ink, the film is transferred to the inked surface by a light pressure. Ether and alcohol are now to be plentifully applied to dissolve off the collodion covering the shadows of the picture, thereby exposing the bare greasy ink surface which may be at once transferred to stone or plate by pressure. The greatest difficulty experienced in this method is owing to the uncertainty of getting an effectual solvent for the collodion film. The nature of the collodion used is the source of the trouble; some samples dissolve off readily, leaving the reduced silver on the ink with all the gradations of tint perfectly rendered, while other samples are so immovable that nothing will effect their dissolution.

3. By forming upon the surface of a collodion negative a deep deposit of the mercurial salt and oxide in intensifying, and for this method there are some descriptions of collodion specially suited, as the image should be entirely on the surface, so that it can be easily wiped off, when the negative exists in that condition it is admirably suited for the purpose, as may be proved by pressing a card coated with ink firmly against it. If it takes up the fugitive particles effectually from the plate, it may at once be turned over on the stone and transferred by pressure, the deposit taken from the plate preventing the ink from contact with the stone, as in 2. By this process an exceedingly minute transfer is obtained, but the utmost precaution is necessary in applying the inked card, as the collodion film sometimes is stripped from the glass, and in that case destroys both transfer and negative.

4. By the following process I get rid of the difficulty of the intervening collodion film (2). Twenty years ago, Sir J. W. Herschell proposed to substitute glass plates for paper in the photographic processes of that date. A flat-bottomed deep vessel was filled with pure water, to which a small quantity of muriate of soda and hydriodate of potassa was added, then a few drops of nitrate of silver. The whole well stirred, when the liquid becomes of a milky appearance. Clean glass plates are then spread over the bottom of the vessel, and the sensitive coating deposits itself in a fine even film on the upper surface of the glass plates; in the course of a few hours the clear water is drawn off by a plug or syphon, but before completely drying I prefer to apply a coating of dextrine and glycerine and nitrate of silver from the ordinary negative bath. When dry it is ready for exposure, under a positive, on glass or waxed paper, and when properly fixed, the deposit comprising the picture can readily be detached from the glass on to an inked card for transferring, or I sometimes transfer the film to the inked surface, before fixing, with advantage.

NOTE.—Referring to the process described at 2, I have to state that on several occasions I have succeeded in charging portions of a collodion negative with printing-ink, after the manner of lithography. It might have been that some greasy vapour or substance had come into contact with the plate either after or before fixing, and was absorbed by the insoluble deposit. Should this prove correct, the process based upon it will be invaluable, as we may then, by exposing an unfixed collodion image to the vapour of hot oil or other greasy substance, the cyanide will, in dissolving off the unreduced silver, carry with it the grease on those parts, but it will adhere to the reduced silver, and afterwards, when wetted, repel the water on those parts, and so become charged with the ink.

THE MANUFACTURE OF PHOTOGRAPHIC COLLODION.*

BY W. L. NOVERRE.

PRECAUTIONS.

The fumes of nitric or nitro-sulphuric acids must not be inhaled, as they are exceedingly poisonous. In carrying an open vessel of the acids from one room to another hold it well up above the head, in this way the fumes will be avoided. Care must be taken that the acids are not allowed to fall or splash on the hands, face, or clothes, as they are very corrosive. They stain the skin and nails yellow, and destroy every kind of fabric. If any acid gets on the hands, rinse in water at once; ammonia, if applied immediately, will sometimes remove the stain from woollen materials. When opening a bottle of nitric acid hold it at some distance from the person to avoid a sudden rush of fumes. When pouring out the acids, place the neck of the bottle in contact with the measure, and let the acid flow out gently to avoid its splashing. Do not attempt to mix the acids in any kind of vessel that would be likely to break from being suddenly heated, and on no account in a bottle. With proper care the operation may be conducted without allowing the acids to come in contact with the hands. India-rubber gloves will, however, afford entire protection, and an apron of green baize will be found very useful to prevent the clothes being splashed with acid. There is no fear of the pyroxyline exploding or taking fire spontaneously during the process of manufacture or after it has been dried, provided that fire does not come in contact with it, and that it is not exposed to a higher temperature than 300° Fah., a little above which it will take fire.

A plan has been given for concentrating weak acids to a suitable strength, by heating till the superfluous water has evaporated. This operation requires care. It must be conducted under a chimney that the fumes may be carried away. Too large a quantity should not be operated on at one time, so that in case of the apparatus breaking less acid will be spilled. It must not be heated too much, or the acid will bump and splash. The dish in which the acids have been heated must not be placed on a cold substance immediately after removal from the hot sand bath, for fear of fracture, and the acid should be placed in a bottle as soon as it is cool that it may not absorb water from the atmosphere. A high temperature will be required for heating the sulphuric acid, as it does not boil till it reaches 572° Fah.

THE PYROXYLINE.

Although the same general directions will apply for making pyroxyline by any formula, the process will be more easily understood if a particular formula is taken as an example. We will therefore select that given by Mr. G. Wharton Simpson, as being simple and yielding very satisfactory and uniform results.

The formula stands thus:—In a mixture of sulphuric acid sp. gr. 1.840, and of commercial nitric acid sp. gr. 1.420, each 6 ounces fluid, immerse 4 drachms of best American cotton, to be left in for ten minutes at a temperature of 150° Fah. The increase of weight after washing and drying should be from 30 to 50 per cent. We will suppose that the specific gravity of the acids has been tested and found correct.

A convenient quantity of acids to manipulate with at one operation is 12 ounces. Everything should be got ready before the acids are mixed. The cotton should be weighed, pulled out into ten or twelve separate tufts and placed on a sheet of paper, close at hand. If a kitchen range is employed for the operation, the cotton may be placed on the hob, or on a chair near the fire-place. Put a saucepan of water on the fire, and allow it to boil gently; have a dinner-plate on the hob, on which the thermometer, the spatulas, and the cover of the jar may be placed; stand a bucket full of cold water near the fire-place; have a breakfast cup at hand, in which the acids may be pressed from the cotton, and a pan

of water to rinse the fingers, in case any acid gets on them. Lastly, take care that all the articles to be used are perfectly dry. When these preparations are complete, and the water in the saucepan boils, measure out the sulphuric acid, and pour into the jar (next the water, when any is required), and then the nitric acid; the jar may be filled on the hob, or on a table near the fire. When the acids are measured out, lay hold of the jar by its handle, and stir the acids well with a glass spatula, to insure thorough admixture, this is important; put the spatula down on the plate, and immerse the thermometer; if the temperature is not sufficiently high, place the jar in the saucepan, leaving the thermometer in the acids, and watch the mercury rise; when it reaches the proper height, move the thermometer up and down, to be sure that the temperature is the same all through. Lay the thermometer on the plate, place the jar of acids on the hob, and immerse the cotton, piece by piece, pressing down each tuft under the acids and against the sides of the jar, so as to expel the bubbles of air. No time must be lost in performing this part of the operation; at the same time, it must not be hurried over, because if the bubbles of air are not pressed out, the acids will be rapidly oxydized, and the cotton dissolved, with evolution of red fumes. The same accident is liable to occur if the cotton is allowed to project above the surface of the acid during immersion. When the last tuft of cotton has been put in, the mass should be loosened with a spatula, to prevent it from sticking in a lump at the bottom of the jar, the object being to let the acid have access to every part, that it may act uniformly on the fibre, it should be worked about in the middle so as to make a space for the thermometer. The temperature generally falls three or four degrees during the operation of putting in the cotton; it will therefore be necessary to place the jar in the saucepan again to raise the temperature to the exact point. The thermometer should be kept moving and carefully watched till the proper temperature is reached, when the thermometer may be withdrawn and the jar placed on the hob again and covered over. The cotton has to be left in the acids for ten minutes; this may be calculated from the time the last tuft was immersed or from the time that the acids were covered over after having been raised a second to the correct temperature. If by the latter method the cotton is found to be too much acted on by the acids, adopt the former plan, and adhere to it in future operations. Perhaps a more accurate method than the above is to allow a few degrees for the fall of temperature during the operation of putting in the cotton, having, on previous occasions, observed the difference of temperature before and after the immersion; thus, to re-immers the 240 grains of cotton divided into 10 tufts in 12 ounces of acid will take about 2 minutes (or less in the case of cotton purified with potash). During this time the temperature will generally have fallen about five degrees, unless the spatula was first heated, which would make a difference of two or three degrees, so that, supposing we intend to work at a temperature of 150°, the cotton should be immersed at 155°, thus allowing 5° for the fall of temperature between immersing the first and last tuft: the jar can then be covered over and left for the requisite time. The thermometer may be left in the acids to see that the temperature does not fall, a hole being made for it in the cover of the jar or a glass plate substituted for it, a space being left on one side for the stem of the thermometer. When working in the manner described the proximity of the jar to the fire will generally keep the temperature the same for ten or fifteen minutes; in this case the thermometer need not be left in the acids, but after 5 minutes it may be immersed to ascertain that the temperature has not fallen. If the jar does not stand near a fire, the temperature will generally fall a few degrees, although it may be prevented by wrapping cloths round the jar. If the temperature falls before the expiration of the 10 minutes, the jar should be placed in the saucepan of hot water till the correct temperature is obtained. If the temperature should have acci-

* Continued from p. 436.

dentally been allowed to rise too high, it may be reduced by moving a cold spatula up and down in the acid.

When the cotton has been immersed the proper time, push the spatulas down to the bottom of the jar on each side, raise the cotton in one lump, and put it into the breakfast cup; hold the cup firmly by the handle, and press as much acid as possible from the cotton with one of the spatulas, pouring it back into the jar; this must not occupy above 30 or 40 seconds; next plunge the cup and its contents into the pail of water, lay hold of the cotton with the other hand and move it rapidly about, distributing it through the water, the ball of cotton when first laid hold of will feel quite warm to the hand, and if not moved about so as to reduce the temperature it would be spoiled. On this account it is important that a large quantity of water should be employed. The water should be changed frequently and the cotton worked about till it ceases to taste acid, it should then be kept in a running stream, or in a large pan of water constantly changed for about 12 hours. Before removing the cotton a piece of blue litmus paper may be kept in the water for half an hour, to ascertain that all the acid has been washed out. Before making another batch of pyroxyline, the jar, measures, and other apparatus must be rinsed out and dried. When the washing is complete squeeze the cotton in the hand, then pull it out and spread it on a clean cloth, roll up the cloth with the cotton in it, and wring it thoroughly; repeat the operation with another dry cloth till no more moisture can be wrung from it, then pull it out into loose tufts, spread on a large sheet of paper and place in the sun or in some warm place to dry. If it is dipped in alcohol after the water has been pressed out and then wrung again it will dry much more rapidly. Artificial heat on a water bath or other contrivance may be used where fire can have no access to the pyroxyline, which is explosive and very combustible; it must be dried at a sufficiently low temperature to prevent decomposition. Some kinds of pyroxyline decompose at a lower temperature than others; 140° Fahr. is generally considered the safest point.

An experienced person can generally tell pretty well when the cotton is washing whether it is of the proper quality, but the most reliable test (providing none of the cotton has been lost in washing) is its weight after the operation; in the formula under consideration, the increase of weight should be from 30 to 50 per cent., the best plan being to try and keep it as near 40 per cent. increase as possible. The cotton must be thoroughly dried before it is weighed or it will appear heavier than it really is. To ascertain that the pyroxyline is quite dry it is a good plan to allow it a few hours drying after it has been weighed, and then to weigh it a second time; this will show at once if it was dry the first time or not. A good pyroxyline for a bromo-iodized collodion for the wet process should be such that five or six grains dissolved in one ounce of a mixture of alcohol and ether will yield a collodion which runs easily on the glass, and forms, when dry, an even, structureless, and perfectly transparent film. If, however, with a view to bring about this condition, the acids have been made too weak, or the temperature has been too high, a portion of the cotton will have become converted into nitroglucose, which substance increases the intensity of the collodion, and causes it to decompose too rapidly after iodizing. These qualities are, however, suitable for a dry process collodion; therefore, if it is found that the pyroxyline has not increased in weight as much as 30 per cent., and does not weigh less than it did before immersion in the acids, it may be used for dry collodion; if the weight is less than that of the original cotton, it will be almost too rotten for a sensitive dry process collodion. If, on the other hand, the increase of weight is more than 50 per cent., it will be found that 5 grains dissolved in an ounce of the solvents will give a slimy collodion running over the glass with difficulty. If diluted to a proper consistency it would be wanting in intensity, and quite unsuitable for the wet process, but it would probably do well for a positive collodion, which ought not to possess

as much intensity as that intended for the wet process. If the pyroxyline is too heavy, a little water must be added to the acids for the next batch: try the addition of a dram at a time to 12 ounces of the mixed acids, till the desired kind of pyroxyline is obtained, and in future operations with acids of that strength, the same quantity of water must be employed. If, instead of the acids of the strength named by Mr. Simpson, we use sulphuric acid, sp. gr. 1.85, and pure nitric acid, sp. gr. 1.420, we shall find that with other conditions the same, we must add 3 drachms of water to every 12 ounces of the mixed acids in order to produce a pyroxyline from 40 to 45 per cent. heavier than the original cotton.

If, on the other hand, the pyroxyline is too light, we know that the acid mixture is too weak, that the temperature was too high, or that the cotton was left in too long.

It may occur that on testing the specific gravity of the acid we have to use, we find it is much weaker than that given in the formula; in that case the quantity of sulphuric acid must be increased according to the strength of the acids; if they are very weak, six parts sulphuric may be required to four parts of nitric, and if this formula will not yield a pyroxyline of the proper quality, the acids had better be rejected.

In making a cotton purposely for dry collodion processes, the temperature may be raised to 165° Fahr. In this case, the weight of the pyroxyline will be nearly the same as that of the original cotton. A pyroxyline for positive collodion may be made by reducing the temperature to 140° or 135°, the increase of weight will then be about 60 per cent.

Pyroxyline should be kept so that the air may have access to it; a tin box with holes in the lid is very convenient for the purpose, it should not be packed too tightly.

(To be continued.)

THE ANALOGY OF THE EYE TO AN OPTICAL INSTRUMENT.

BY J. Z. LAURENCE, F.R.C.S., M.B.*

THE analogy of the eye to an optical instrument has, from the earliest times, attracted the attention of philosophers; hence their efforts to apply the ordinary laws of optics to the resolution of the various problems of vision. By none have these been adapted with greater felicitude than by our great countrymen, Young and Porterfield. But nearly all these researches referred to physiological optics. The study of the pathological deviations of the dioptric system of the eye is of comparatively modern growth. All I know is, that when I was a student, the knowledge I had imparted to me was limited to the fact that concave glasses improve myopia, convex ones, presbyopia, and that the selection of the precise power required for any given case was an entire matter of rude empirical trial.

The basis of the exact knowledge we now possess of pathological optics were the discoveries of Cramer and Helmholtz, who have for ever solved the much-veiled question of the adjustment or accommodation of the eye to different distances, when they proved it to depend on a change of convexity of the crystalline lens, and that this was effected by the ciliary muscle. We then come to the researches of Professor Donders, of Utrecht. He, for the first time, insisted on the absolute necessity of separating the two factors, refraction and accommodation; to adopt the language of mathematics, the 'constant from the variable.' None but those who have intimately studied the subject can form any conception of the importance of this one simple step: of the precision it has conferred on our ideas—how it has smoothed the path for all future researches. Donders recognises three conditions of refraction—1st, normal; 2nd, excessive (myopia); 3rd, deficient (hypermetropia). The

* From an able and eloquent oration on "The Progress of Ophthalmic Surgery," delivered by the author before the North London Medical Society, and just published by Churchill.

first step in the investigation of any given case is to refer it to one of these three classes, then to estimate the precise amount of refraction—the 'power'—of the eye. Having thus determined the constant, we may examine the variable—accommodation—and thus finally form a complete analysis of the case. To adopt a familiar simile—if we wished to investigate the qualities of a telescope, we should first test its powers of defining distant objects, as the heavenly bodies, and then those of adjustment for near objects at variable distances. The first elements of science appear in the form of isolated facts. As these multiply, a kind of mutual connection appears possible. Possibility becomes successively probability; probability, certainty. And thus the individual truths of science, like the wheels and pinions of the engine, become all subservient to one great common end. In no branch of science has this been better exemplified than in what has almost become a speciality of a speciality—viz., our knowledge of the deviations of refraction and accommodation of the eye. Within the last year, Donders has again added to our knowledge of this subject by an elaborate treatise on Astigmatism.

Astigmatism (coined by Professor Whewell, from a privativum and *στίγμα*, point=focus) is an inequality of refractive power in the different meridians of the eyeball—understanding by the term meridian, as in astronomy, a great circle passing through the poles. Practically, we may limit our investigations to the horizontal and vertical meridians of the eyeball. Thomas Young, in 1793,* was the first to discover this peculiarity in his own eye; this "in a state of relaxation collects to a focus on the retina those rays which diverge vertically from an object at the distance of ten inches from the cornea, and the rays which diverge horizontally from an object at seven inches distance."† Consequently, the refraction of his globe was greater in the horizontal, than in the vertical meridian. In 1827, Professor Airy published a remarkable instance of the same anomaly in his own (left) eye.‡ In this, the furthest point of distinct vision for vertical rays was three and a half inches; for horizontal ones, six inches; the eyeball thus being nearly double as myopic in the vertical, as in the horizontal meridian. To Airy likewise belongs the merit of first having applied cylindrical glasses to the cure of astigmatism. This has been shown by exact measurements to depend generally on an inequality of curvature of the vertical and horizontal meridians of the cornea. It may, however, as in Young's case, originate in an irregularity of curvature or position of the crystalline lens. Astigmatism is remediable by cylindrical lenses. These represent sections of cylinders parallel to their axes. Such lenses have the peculiarity of exerting a lenticular (refracting) influence on rays striking them transversely to the axis, allowing those striking them parallel to the axis to pass through no more refracted, than they would be by a piece of plane glass. Thus we may add to or subtract from, by cylindrical, convex or concave lenses, the refractive power of one meridian of the globe, leaving the other unchanged, and thus restore the equality of refraction in the two meridians—correct the astigmatism.

Up to the period of Donders's recent researches, only eleven cases of this optical defect had been recorded. He has shown that astigmatism is really a very common disturbing cause of vision, and that many cases hitherto but imperfectly correctible by ordinary (spherical) lenses, are almost completely so by cylindrical ones, either alone or conjoined with spherical ones.

NATIONAL PHOTOGRAPHIC PORTRAIT MUSEUM.‡

PHOTOGRAPHY stands in the foremost rank as a great civilizer: it enters into every grade of society, from the Queen on the throne to the peasant in his humble cottage; and it

affords to those engaged in commerce a cheap and faithful means of distributing exact copies of their productions for the benefit of all. The most intricate mechanism is copied as easily as the most simple; the artist avails himself of its wondrous powers, as does also the architect; and the lecturer employs it with the magic lantern as the means of showing instantly to his audience places and things that, with the most eloquent tongue, he would be utterly unable to describe.

We have used it selfishly to supply our own wants, and oftentimes to gratify our own vanities. But we may, if we will, use it for a purpose far more noble than any it has yet been applied to. By its aid we may raise a monument to all men and women that are great and good, and one that shall be more lasting and far more truthful than the cold and unimpassioned marble; in fact, we can secure the perfect image of the human being instinct with life, and so preserve it that it shall be a monument for all time to his or her memory, that will afford to generations yet unborn the high gratification of looking upon those who have lived centuries before themselves, and who, by their patriotism and genius, have helped to make the world what it is. What would we not give to possess faithful portraits of the illustrious dead? that we might look upon them face to face as they walked the earth. Had the art been known in the days of Socrates, Dante, or Shakspeare, we might have possessed photographs of these and thousands of others; but as we cannot raise the images of the mighty dead, we may preserve for all time the illustrious living.

It will be asked how can all this be secured. Very easily, as will be seen from the following suggestion of Mr. MacLachlan:—Photographs, no doubt, at present are not to be depended upon as lasting memorials, but the original negatives are as lasting as the material (glass) upon which they are taken. The plan proposed is to secure the negative plates of great men, and have them placed in a museum for safe keeping, properly authenticated, attested, and registered by the mayor or other authority of the place where they are taken; and, to provide against accidents, it is proposed to secure in every instance, three plates of the same individual, which can easily be done, as the original one can be always reproduced at pleasure.

The object of securing these plates is, that one may be kept within the institution, and the other two lent, at the discretion of the authorities in charge: for instance, to any author of eminence for book illustration; and by that means the memories and images of those who have been great and passed away would be transmitted faithfully to all posterity. In almost every instance there would be several portraits of the same individual in different museums in the country, affording a still greater security for their permanent preservation. All local celebrities might be taken in their own towns and deposited in the museums of their respective localities, and should a time arrive when their genius became acknowledged by the world, then they might claim a shrine in our great National Museum. There would necessarily be a few simple rules to guide us in the selection of the proper kind of plates to deposit, which it is needless to enter into here.

Portraits can be taken so small that thousands of them would not occupy one square foot, and at the same time could be enlarged to life or any other size at pleasure.

As to cost:—Mr. MacLachlan offers his best services in photographing any persons who may be deemed worthy, esteeming it an honour, and he believes his brothers in the art would assist as freely as himself.

The space required for the due preservation of these negatives is very small. As many as five or six thousand could easily be stowed, ready for reference at all times, in a couple of presses of ordinary size.

PHOTOGRAPHIC PICTURES AND ILLUSTRATIONS.

[Some months ago the *London Review* published a very offensive and unjust article on photography. It has recently atoned for this by the issue of one or two articles at once just,

* "Philosophical Transactions," vol. lxxviii. p. 169.

† "Philosophical Transactions" for 1801.

‡ "Transactions of the Cambridge Phil. Soc." for 1827, vol. ii. p. 267.

§ *Journal of the Society of Arts.*

appreciative and instructive. We publish the last first, and shall add the other, if we have space, another week.—Ed.]

LAST week we dealt with photographers in their power of copying. What shall we say to their power of producing original pictures. This, with merely mechanical and optical means, would appear an almost hopeless task, and that attempts of this sort usually fail, is not surprising. Rejlander has, however, produced some very clever things; not so thoroughly perfect as we could wish, but fine indications worthy of high rank. Rejlander has all the genius for seizing on thorough artistic incidents. He groups his figures and poises them with admirable skill, raises somehow in his subjects the very look, action, and point required, and catches the happy moment with the quickness of the lightning-flash. But he is to us rather a slovenly chemist and spotty manipulator.* These are harder terms than he deserves; for perhaps it is that the subjects of his witty or genre pictures and the way they are handled make us angry with the artist for not surmounting the defects photography itself is heir to. Who can look at his "Participle-catching" and his "Participle-caught," and not enjoy it as much as one of Hunt's quaint water-colours? You see the boy's hand stealing gradually towards the fly; then you can almost hear the insect buzzing in it. In his "At Work," "At Rest," "At Play," you comprehend alike the grey-haired grandpapa and the flaxen-haired child. His "Street Fiddler," and his "Night in Town" are powerfully painful, the "dark within and light without" comes touchingly from the blind woman's sightless eyes; while the poor ragged boy sleeping on the door-step, his comfortless night in town becomes the more touching from the incident that gave rise to the picture,—"Take him away!" unfeeling ordered the well-to-do tradesman, returning in the small hours of the night from his carousal, directing the policeman to the poor, shivering outcast. "Throw the light of your lantern upon him," said the passing photographer; and the poor lad went his way rejoicing, with half a crown in his threadbare pocket, instead of finishing his sleep with drunkards and thieves in the station house. Six times on his head for a halfpenny gives the topic for "A Day in Town; and good as this is, it is beaten in humor by, "Jim, is it a good 'un?" in which the knowing look of the boy, as he bites the sixpence, is exquisite. "The Two Ways of Life" is another composition picture, by Mr. Rejlander, of a more pretentious kind, composed of very numerous figures telling the two stories in forcible terms, and replete with incidents and expression.

What we have so far noticed are what may be called in photography works of high art. There are, however, more familiar phases of photography; and these are the more important as it is the familiar and common uses of an art that produce the greatest and most extensive effects. Of these, two will instantly occur to every mind—the *cartes de visite* and the smaller class of stereoscopic views. These are not only an industry in themselves, but have given rise to other extensive businesses in the manufacture of albums and hand-stereoscopes. The small portraits known under the former title should not be regarded in the aspect of supplanters of the fine miniatures of the old school of miniature painters, although unfortunately they are so, but rather should we take a wider view, and regard them as annihilating those disgracers of art to whom the less wealthy were forced to apply to gratify those desires to preserve something of the forms and faces of those who were near and dear. In the olden time it was some parent, child, or friend whose features were thus perpetuated; and how common and how deep were the regrets in many a breast that nothing more like the departed remained! Now the humblest amongst us may cherish the remembrance of parent or child; and in the setting of life, in the space of a pocket-book, we can enter, visually at least, again into the presence of long-lost friends, and recur to many a long-past scene. The family portrait, too, in ponderous golden frame, hanging from the wall, is either ever painfully present or familiarly unnoticed; but the card-

like photograph comes out in silence and solitude at the holiest moments of uninterrupted thought. And so cheap and so facile is the photographer's portrait-taking, that even curiosity, as well as affection, can be gratified.

Mr. Swann's casket portraits are very pretty and ingenious articles, suitable for presents or for mementos of those closer friends or relatives of whom we might wish to have some special token of remembrance. They are small photographs, carefully coloured and mounted on two sides of a glass prism set in a casket or case of any size, from that of a *châtelaine* ornament to three or four inches in height, the effect of the prism being to commingle, in a perfectly stereoscopic manner, the two views, and, on looking into the casket, a life-like bust is seen.

The numerous views of places and scenery, especially the stereoscopic ones, are sources of great instruction and knowledge, and amongst the most entertaining and beneficial amusements ever introduced into our homes. Of these, those by Wilson of Aberdeen are pre-eminent for every artistic and pictorial quality—as witness his "Hawthornden," "Lower Fall of Moness, Aberfeldy," "A Bit in the Trosachs," "Ben A'on—Loch Katrine," "A Bank of Ferns," "Lincoln Cathedral," "Stonehenge," and "Land's End." The Stereoscopic Company supply us with fine American scenes—"The Broadway, New York," "Wall Street," "Hudson River," "Mountain Gorge in the Catskill," "Niagara," and with views in Canada; and from this and other sources we can obtain pictures of other lands, to study the physical geography and geology of places we could never have the time nor funds to visit.

But all the branches of photography, except portraits and the trade in views along the usual tourists' routes, are at present desultory and capricious in production and sale, although we think it only wants some few practical suggestions to turn the vast amount of material produced to useful and practical ends. The illustration of favourite authors or special subjects with reliable photographs even of the ordinary kinds, would be far preferable employment than potato-mania for young ladies; and even men of intellect and science would not charge efforts in this way as useless and idle. A Bible illustrated with photographs of the Holy Land, Egypt, and of objects referred to in its stirring passages, would be a great inducement to its study by the young, and profitably instructive to many of maturer years. A geography illustrated with nature-printed views of foreign lands, mountains, rivers, and cities would be highly interesting; and even a favourite novelist or poet would not lose in attractiveness by being intercalated with views of the principal scenes. Any particular book or subject might thus be adorned with appropriate views and portraits; just as Mr. Bennett has illustrated his "Ruined Abbeys and Castles on the Wye," and has made a collection of the principal scenes in Scott's "Lady of the Lake." Mr. Lovell Reeve, too, has effectively used photographs in Mr. Piazzi Smyth's "Teneriffe," and is doing so now in his "Biographies of Eminent Men." The two portraits of Carlyle and Tennyson by Mr. Jeffery, about double the size of ordinary *cartes de visite*, are very good and of an admirable size for books or collections of biographies. They form, we believe, part of a series to be published by Messrs. Marion.

A fashion of this kind, for illustrating books and journals, would involve the necessity of publishers selling their views unmounted. The present cards are liable to be lost and to get damaged, which would not be the case if the views were pasted like prints in a scrap-book, diary, or volume. It may be well, however, to remind those who may take a fancy for our suggestion, that mounted photographs can be easily unmounted. They are fastened on to the cardboard with starch—common paste being deleterious—and by simple immersion in warm water, can be safely peeled off without injury, and then remounted in the proper manner. At present, no unmounted photographs can be bought, unless by special order; but the Messrs. Marion, of Soho Square, are contemplating the issue in that state of the very fine series of views in Spain taken not long ago by the late Mr. Clifford, and which remarkably confirmed the opinion we entertained of the value of photography in architecture. Some of the objects selected by Mr. Clifford in his "Scramble through Spain," are perfectly marvellous for their intricacy of detail, as, for example, the tracery of the door of the Hall of Justice at Grenada, the court of the "Casa de Pilatos"—a palace built in the sixteenth century by Don Guizquez de Ribera—and some details of the principal courts of the principal courts of the Alcazar in Seville. Such elaborate

* One word for Mr. Rejlander. Some of his pictures may be charged with slovenly manipulation; but it should be remembered that he frequently works alone, without assistance, and that he is so absorbed with the *thought* in his picture, and with that which belongs to the artistic expression of that thought, that he occasionally loses sight for a time of the mechanical details upon which neatness and spotless manipulation depend. Mr. Rejlander has produced, notwithstanding, some of the finest pictures, *photographically speaking*, as well as in an artistic sense, which have ever been issued.—Ed. PHOTOGRAPHIC NEWS.

subjects could only have been executed by the finest artists, and pictures by any but first-rate men would have been valueless. They were little likely then to have been produced, and photography may be well allowed to do for us without envy what artists would not; and while art can give us pictures beyond the best efforts of the chemist and optician, her followers should be rather urged to grander efforts than to jealousy by the near approach to her realm which modern photographers have by the most earnest efforts attained.

The trade in small photographs is enormous. We were informed by one wholesale house that their monthly sale was 50,000, and this rate could hardly be exceptional. The power, therefore, for good in this branch of industry must be vast indeed.

That there is a tendency springing up to collect photographic views of geographical places, physical scenery, and the finest architectural buildings, is shown by the "latest novelties" in photograph albums. Some of the charming views by Wilson are of very suitable size (6 inches by 4 inches) for illustrative purposes, such as the series he has just executed of "Windsor Castle" and "Roslyn Abbey," the sharpness, precision, aerial perspective, and details of which are rendered with the greatest skill.

Special collections of stereoscopic photographs of any particular class of subjects or objects would also present valuable as well as entertaining results, and introduced in social parties would give rise to much interesting conversation and mutual instruction. Without attempting to develop any new or useful branches of the great trade in photography, we are satisfied now, while publishers are despatching their photographic artists in various directions for new views for the coming season, with pointing out the mines of wealth that at present lie unworked in the publishers' portfolios, and to the stock of which every day's labours are adding. Amongst the first in-comings of these labours for the approaching season, we have already seen some magnificent views in Rome, Venice, Florence, and Pisa, by the Bissons, imported by M. Victor de la Rue. All these are large in size, and many (for there are fifty in all) are of subjects familiar to us through pictures and prints,—such as the "Palace of St. Mark, at Venice," the Leaning Tower of Pisa," the "Cathedral of Milan,"—besides which they may be well placed for comparison, when the overt veracity of these new views of old subjects will not be their least valuable feature. The "Arc des Orfèvres," the "Three Columns of Jupiter Stator," the "Basilica of Constantino," and the full view of "St. Peter's in Rome," the beautiful details of the "Gate of La Loggia," and the "Central Entrance of St. Mark, in Venice," the exquisite minutiae of the panels of the Baptistery gates (fifteenth century), the "Campo Santo," in Pisa," in this series, will assuredly reckon amongst the finest productions of these accomplished artists.—*London Review.*

Correspondence.

FORMIC ACID IN THE DEVELOPER.

SIR,—Can you find space for a few lines on the subject of Sergeant Moss's letter, in your last?

He arrives at the conclusion that "formic acid, added to pyrogallic acid in the developer, as recommended by M. Claudet, is quite as powerful as the ordinary iron developer."

M. Malone, writing of M. Claudet's suggestions, (*vide* article by M. Malone, at page 300, *British Journal*, for August 1), distinctly states that "the avoidance of bromine salts in the collodion is absolutely essential to success." Sergeant Moss tells you he makes his experiments on the developer recommended by M. Claudet "with a collodion containing a considerable proportion of bromine salts."

Sergeant Moss, before entering into experiments with delicate processes, such as the use of formic acid involves, should have known at all events the fundamental rule that to obtain the best results with pyrogallic acid, a simply iodized collodion is required; and, professing to make experiments on M. Claudet's ideas, he should, at all events, have adopted his formula, and worked with them as a basis.

The writer, therefore, has neither made his experiments according to the formula recommended by M. Claudet, as regards pyrogallic acid, nor according to the formula with

iron, to which I myself called attention in your journal some two years since.

And he produced a better negative with the ordinary iron developer than with a developer containing pyrogallic and formic acids!

But having commenced, as I pointed out before, with a collodion wrongly sensitized, his experiments are comparatively valueless.

Even in the original formula for the employment of formic acid in conjunction with pyrogallic acid, published by Mr. Maxwell Lyte many years since, a simply iodized collodion is included.

I must apologise for taking up so much space in alluding to experiments carrying their own inutility so plainly stamped upon them, but I do so in the interest of amateur photographers in general.

I have many letters addressed to myself asking for advice as to the employment of formic acid, as suggested by myself, and doubtless M. Claudet has as many addressed to him, showing the interest taken in the subject. An amateur, reading Sergeant Moss's letter, and not being himself well up in the subject, would naturally conclude that M. Claudet recommends bromo-iodized collodion in his formula. Thus he would be led into a serious error, and find himself disappointed in the process, and would do no justice to M. Claudet's ideas, or, indeed, to the employment of formic acid in general; and in order, as much as possible to prevent novices from being misled by such inexact experiments and conclusions, I address you these few lines.—Truly yours,

H. STUART WORTLEY.
Lieut. Col.

September 14, 1863.

RELATIVE EXPOSURES FOR VARIOUS PROCESSES.

SIR,—I have before addressed you about information needed to enable one to judge of and fairly work different processes. I have now been hunting all your volumes as well as picking up such information as I could get from Hardwich. I have endeavoured to use mainly the information derived from successful workers, where available, and have made a table of exposure constants for the different processes, which will, I trust, be useful.

The equivalent focal length, diameter of stop, and exposure being known, I have found the constants by multiplying the seconds of exposure by the square of the diameter of the stop, and dividing by the square of the focal length.

To use these constants we have only to multiply them by the square of the focal length of the lens we desire to use, and divide by the square of the diameter of stop, to obtain the seconds of exposure.

I do not suppose this will be rigorous or suit all times, but it will be a more reliable guide than the rough estimator of "6 times the exposure of a wet plate," &c., which we so often see. I have spoiled many plates and wasted much time on dry processes, mainly, I believe, from not knowing what the rough exposure should be. You will see tannin and honey is the only process coming near wet collodion. The great objection to honey is its variability. The main accelerator in it is, I apprehend, the grape sugar, but that constantly passes into the crystallized state. In your number of April 2nd, Mr. Verity gives a formula which should be definite in its results. Would he publish more information? The maker could well give the equivalent focal length of his lenses, and if he would give a few exposures for good pictures under average circumstances, with focal length of lens, and stop's diameter, we could glean more from this than from rough comparisons with wet collodion, which varies more than a dry process in sensibility, as far as I can judge. Numbers so obtained are fair exponents of relative sensibility in different processes, and carefully collected data (if photographers would condescend to give them in numbers) would settle various matters in doubt.

Opticians would soon publish their equivalent focal lengths if customers would ask for them, but as each lens, to some extent, varies, it would be desirable for careful men to ascertain the equivalent lengths of their own lenses when purchasing. I may mention that the wet collodion data are by myself, they are derived from work with a Ross orthographic 12.5 inches focal length, a Voightlander portrait lens 11.5 focal length, 3 1/4 inches aperture, and Dallmeyer's 1 B lens, 6 inches equivalent focus, as nearly as possible.

I fear I have exceeded my tether, but I am very anxious to urge on photographers the necessity of passing from indefinite opinions to definite numbers in other matters, besides making solutions. We are too much in the habit of talking of "lumps the size of horse beans." One soon can estimate weights and measures sufficiently for home use, but we must express weights, measures, and time in terms of known units to be of use to our neighbours.

Exposure Constants for Landscape Work in Fair Light.

Wet collodion (fir trees near at hand)	0.080	Iron developer.
" (viney in the open near)	0.011	Improved do.
Fothergill process (the mean of several)	0.400	
Collodio albumen	0.442	
Metagelatin (iron developed)	0.617	} Maxwell Lyte.
" (pyro developed)	2.467	
Albumen (a dull day)	1.04	Mr. Archer.
Tannin (fair light)	0.45	Mr. Sutton.
Tannin & honey "	0.049	Mr. Wharton Simpson.

An approximate exposure will be got by multiplying the constants by the square of the equivalent focal length of the lens, and dividing by the square of the diameter of the stop, both data being in terms of the same unit.—Yours truly,

AN AMATEUR IN INDIA.

July 27th, 1863.

Photographic Notes and Queries.

QUERIES ON GOLD TONING.

SIR,—Would you kindly give your readers a few words of explanation on the following matter, viz., the utility of *alkaline* salts in a toning bath. Presupposing the gold to be either neutral or neutralized, we have carbonate of soda, bicarbonate of soda, phosphate of soda, borax, or bichlorate of soda, acetate of soda, citrate of soda, carbonate of lime, chloride of lime, chloride of calcium, carbonate of potash, citric acid, and soda (the old ginger-beer process), and, perhaps, before the year is out, a host of others, all recommended by various operators, each having his favourite, and yet all "unstable as water." In fact, no dependence to be placed on any of them. Now, what I want to know is, why will not a *neutral bath* of chloride of gold and water *without any* of the foregoing preparations do, and do well? What is the virtue in each, or any of these salts, or a combination of two or more of them? Several firms are now advertising *neutral chloride of gold*—will it do *without these additions*?—if so, no greater boon can be conferred on the photographic public. I am tired of seeing gold becoming purple, and falling to the bottom. My opinion is that the best plan is to make a bath at the moment you want it—say, of soda and gold, which will answer for an hour or two. But the *use* of these salts in the bath is what I wish to know.—Yours,

AN OLD SUBSCRIBER.

P.S.—The great question is—If we can get a *neutral chloride of gold* in the market, is there any necessity for any addition?

[The object of the various alkaline additions to chloride of gold is to produce a certain decomposition, to destroy the feeble combination which exists between the gold and chlorine, so that the former may be deposited upon the print. If this decomposition were effected without any other base for which chlorine has affinity being present, the liberated chlorine would attack the silver in the print with great energy, producing meanness and excessive bleaching. If soda or a similar salt be in solution, the chlorine combines with it;

and although in virtue of its superior affinity for silver it will eventually combine to some extent with the latter, the action is controlled and regulated. If a solution of chloride of gold were perfectly neutralized with carbonate of soda, it would too readily be decomposed and would not keep, unless free chlorine were present. Hence a solution of chloride of gold neutralized by the addition of chlorineted lime will keep. The addition of acetate of soda and similar salts produces the required decomposition slowly, by the strong acid with gold displacing the weaker acetic acid and leaving it in solution with the neutralized, or partially neutralized, chloride of gold. As the colour of the print depends upon the size of the molecules of gold, and as the size is affected largely by the mode and rapidity of its reduction, different results are produced by different salts added, and by the proportions in which they are added. The plan you prefer of adding carbonate of soda to the chloride of gold often answers very well, but rarely produces the best results. It has, moreover, the disadvantages of producing meanness if used too soon, of not toning if not used soon enough, and of not keeping prepared for use.—Ed.]

CHEAP GLASS ROOMS.

SIR,—If Colonel Stuart Wortley would give, through the medium of your journal, a description of his cheap operating room, *i.e.*, the particular measurement, construction and conveniences, he would greatly favour many intending builders, as well as, sir, yours,

J. W. T.

Mirfield, September 5th, 1863.

INSENSITIVE SPOTS IN TANNIN PLATES.

SIR,—In your paper of the 28th August, I find your correspondent, "Tyro Tannin," in difficulties about insensitive spots in the negative. I have been troubled with the same, and it cannot be the gelatine, as I never use it, thinking I can get better pictures without it. I use only a line of black varnish round the plate before developing. I find in the centre of each spot a small speck, whether dust or not, I cannot say; but it appears to repel the tannin from it all round.

Inclosed is a specimen without gelatine for your inspection.—I am, sir, yours,
ANTI-GELATINE.
[The prints enclosed are very satisfactory.—Ed.]

LIME TONING.

SIR,—The lime toning question being one of the absorbing topics of the day in the photographic world, if you will kindly permit me to record my experience in that direction, the result may be of service to some of my brother amateurs in the art photographic. I, like many others, tried my hand at the different formulæ, given from time to time through the columns of the PHOTOGRAPHIC NEWS, with but little or no success; not that I ever had a *mealy* picture (and I may here remark that I have never had a *mealy* picture since I have used acetate of soda in my bath for the papers), but I found the *bleaching* spoiled all my best prints. After trying this, and trying that, at last I made a bath as follows:—

Beaufoy's concentrated chloride of lime	1/2	drachm
Acetate of soda	1	"
Chloride of gold (Hockin's)	2	grains
Distilled water	20	"

After mixing, I put a piece of common chalk into my stock bottle; in two days, my bath began to work. I enclose a print toned therein.—Yours obediently,

AN AMATEUR.

[The print enclosed is a very satisfactory one, and the tone excellent.—Ed.]

Talk in the Studio.

PHOTOGRAPHS OF GLACIERS.—The Austrian correspondent of the *Daily Telegraph* says:—"A photographic expedition started lately from Vienna for the Clockner, and the formidable glaciers surrounding the system of the Saltzburg and Tyrolese Alps. The enterprise has been hitherto crowned with signal success, and promises to yield a considerable number of faithful delineations of the upper world. Of the Clockner, eight different views have been taken at the height of 11,000 feet.

PHOTOZINCGRAPHY.—We see it is announced that the whole of Domesday Book, relating to thirty counties, has now been reproduced in fac-simile by photozincography, under the superintendence of Colonel James, at Southampton.

PRESENTATION-PRINT OF THE PHOTOGRAPHIC SOCIETY.—The members of the London Photographic Society are fortunate: for their next year's subscription they will become the possessors of a picture of at least the full intrinsic value of the money, and which will derive the added value derived from selectness, as its circulation will be confined exclusively to members of the Society. The picture is Robinson's charming composition, "Bringing Home the May." The society's *Journal* says:—"The presentation-print for next year will be one of the finest photographic pictures which have ever been issued. Many of our readers have seen, and all of them have heard of Mr. H. P. Robinson's last and finest composition, "Bringing Home the May," a picture which has won golden opinions from both French and English critics as the finest photographic composition-picture ever produced. The size of the original picture is about forty inches by fifteen inches, and it was published at twenty guineas. Notwithstanding the unprecedented price, Mr. Robinson received a large number of orders, which his other engagements did not permit him to fulfil. With a view to prevent disappointment, he resolved to issue it on a smaller scale, the size being about twenty inches by eight inches, and the price a guinea. The very fine negatives and copyright for this issue Mr. Robinson has handsomely presented to the Photographic Society, and each member for the coming year will receive a mounted copy with india-tinted margin. As the photograph will not be published in any other form, members of the society will have the exclusive possession of this picture."

MEAGHER'S CAMERA.—The magnificent camera presented by Mr. Meagher for the benefit of the Lancashire Fund, and which was declared by several of the jurors to be the finest camera in the International Exhibition, was drawn for a few days ago at Twickenham House, the residence of Dr. Diamond, Secretary of the Photographic Society, when we, with a few other members of the society, were present. The names of the subscribers, one hundred in number, had been entered in a book in the order of their subscription. One hundred slips of paper, in one of which the word *prize* was written, were placed in one hat, and one hundred slips numbered from 1 to 100 in another. The drawing was confided to two young ladies, who each drew a slip, coincidentally, from the two hats, and announced its contents. Eighty-seven blanks were drawn before the prize turned up; and when it did so, number 10 came at the same time. This was found, on examination, to be one of the numbers of two shares taken by Mr. William Brown, a mining engineer, now in Spain. Mr. Brown was one of the earliest collodion photographers, and a friend and associate of Mr. Archer's, and it is somewhat odd that he made with his own hands the first camera specially adapted for collodion plates. Shortly after the discovery of collodion he left England for the Australian Continent, Feegee, &c., only returning to Europe last year.

To Correspondents.

- X. Y. Z.**—Where the negative is intensified after it has been fixed and dried, it is important to use a collodion which adheres well to the plate. Where a tendency exists, however, for the film to leave the plate during intensifying it is desirable to paint the edge for about one-eighth of an inch with varnish. The late Mr. Lacy used to intensify all his negatives after drying; and when any tendency to loosen was manifested by the film, he gave it an edging of Huches's black varnish. 2. Blanchard's collodion may be intensified after fixing and drying with great advantage. 3. The Sahnce varnish is the hardest with which we are acquainted.
- P. C. J.**—Your pictures are very creditable for a photographer of only two months' practice. The greatest fault is in the lighting. You have too much diffused light, and it is too much in front. The consequence is a want of force and of good modelling. No. 5 is your best picture, but in it there are a few spots which look very like under-fixing, the hypo probably having been old and exhausted. Your background is too much cut by straight lines; especially avoid the light-coloured nondescript ornament to the left, which appears in each. There is some want of brilliancy in the prints, but it is chiefly due to the character of the negatives which lack a little force. Take care to avoid any deposit of the deep shadows. The acetate toning bath will probably give you, as a novice, the least trouble.
- R. SMITH.**—We have received the varnish, and will try it on the first opportunity we can command.
- W. COLESWORTH.**—The sitter placed with his back to the south, with the light from the north-east, falling obliquely on him, would answer very well. Mr. Rejlander states that he finds sufficient light in his glass room. But, remember, that it is in a fine position, with a large expanse of open light. We should, as a rule, recommend having the capability of getting a little more light. Mr. Rejlander's address is 7, St. George's Terrace, Maldon Road, Haverstock Hill; but we would suggest that the time of

professional photographers is generally very valuable, and it is scarcely fair to expect them to write private letters describing their arrangements, especially when they have already fully described them in print.

NORMA.—The only mode in which we see that you can reap any benefit from the discovery of a valuable dry process is by preparing the plates for sale. If you can prepare dry plates to be certain and rapid, they would doubtless sell. We shall be glad to receive your further promised communication.

OSK WHO IS GOING TO TRY THE DRY.—There is very great variety in the keeping qualities of plates, both before and after exposure. As a rule, it is desirable to develop as soon as possible after exposure. We have heard of tannin plates keeping a week or two after exposure without injury, and of collodio-albumen plates keeping longer still. But they should be carefully sealed from damp, &c., as well as light. Some plates spoil if not developed within a few hours of exposure, the image latent being gradually destroyed.

A.—The stains in your print are caused by hyposulphite of silver. How it came there is less certain. The spots have scarcely the appearance of those caused by imperfect fixation. They rather appear as though some trace of nitrate of silver had come into contact with the prints before the hypo had been removed. This would not necessarily show in an appreciable degree until they had been exposed to the light for some time, which might not occur until after they were mounted. The stain is in all respects characteristic of hyposulphite of silver. On wetting the spots and exposing them to sunlight, those which were faint and scarcely perceptible became very much darker, and had the dirty yellowish brown and mottled effect so commonly produced by the decomposition of hyposulphite of silver. 2. As photographs they are very good indeed. There is a little excess of top and front light, but, with this exception, they are excellent. 3. It is evident that your ether was not good. We have known the addition of had ether to collodion produce insensitiveness and fogging. It does not necessarily follow, however, that it was bad when sold to you: remember that ether, when kept in a partially filled bottle and in the light, becomes acid and unfit for photographic purposes. Your bath may be rectified by the addition of bicarbonate of soda until a slight permanent precipitate is formed; then expose to the sunlight for a few hours, filter and try. If necessary, then add a little acid. It will probably work all right.

A. B. C.—From our own experience, and the mass of evidence which comes under our attention, we should say decidedly No. 2.

P. M.—Some samples of paper have a much greater tendency to lose their tone in the hypo than others. When a sample is found to give this result the only plan is to tone a little longer before fixing. It is also most common with prints from weak negatives which do not admit of deep printing or bronzing of the shadows. It is possible that the vapour of coal tar in the dark room might cause fogging; but we do not see any objection to it for coating opaque parts of the studio.

HARRISON FRODSHAM.—Methylated spirit may be used in the developing solution without any disadvantage. 2. Common vinegar might be used instead of acetic acid in the developer, but its strength is very uncertain, and a large quantity would be required. 3. If common acetic acid be used instead of the glacial acid, a larger quantity must be used.

TYRO.—Volume VI. of the PHOTOGRAPHIC NEWS is unfortunately out of print.

THOMAS K. LANE wishes us to state that a print from a tannin plate of which we spoke highly in a recent number, was not printed by himself but by Mr. Warner, of Ross.

W. BARTHOLOMEW.—We are uncertain as to where you can obtain albumenized paper salted with barium. Mr. Lampray will prepare you some if you require a quantity. Mr. Enghand prepares his paper with half barium salt and half ammonium, but we do not know that it is for sale. Mr. Heisch (Murray and Heath) used at one time, we believe, to prepare a barium paper, but we do not know whether he does so now or not.

B. W. B.—The want of sharpness in your picture is due to the figure having moved very considerably. There has been a lateral movement of at least two inches in this case. It is also doubtful whether it was properly focussed. You appear to be exposing altogether too long. Two minutes' exposure at midday in fine weather seems monstrous. One-sixth of that time would be nearer the mark.

J. FOOTE.—Your prints are very good. The negatives are a little hard. A trifle longer exposure and less intensifying would have been better, but the prints are of good quality.

A. DEANY.—If you wish to albumenize your own paper, use 8 grains of chloride of ammonium to each fluid ounce of white of egg, very thoroughly beaten; and if you want a high surface do not add any water. 2. If your prints are carefully washed, before immersion in the toning bath, there ought not to be any precipitation. A black precipitate in the toning bath is probably metallic gold.

JOHN DAVIDSON.—We do not know any one in this country who sells micro-photographs mounted as charms. Should we hear of any one we will let you know.

J. CASARTELLI.—We will make some inquiry about the claims of Mr. Potter to the invention of Eden's camera, and probably insert your letter in our next.

R. T. BACH.—We will examine the glass, and report in our next.

C. M. SMART.—The silk appears to be perfectly non-actinic, but it obstructs a great deal of light.

Several Correspondents in our next.

PRINTING IN AMERICA, FUMING, ETC.

THE system of treating excited albumenized paper with the fumes of ammonia which has been described in our pages in various extracts from American journals, has not obtained a permanent place in the practice of printing in this country. When it was first announced in our pages as the independent discovery of Mr. Penny, of Cheltenham, a few experimentalists gave the system a hasty trial, and condemned it. Others did not consider it worth a trial, and virtually the plan has been ignored or abandoned.

Nevertheless, we are by no means certain that the fuming system has received justice, or that to disregard it is quite wise. Let it be remembered that it is not a mere suggestion which has been tried on a small scale by a few enthusiastic or crchetty experimentalists. It is the method adopted not only by many of the ablest amateurs in America, but also in many of the largest professional establishments, and answers commercially. We have recently had an opportunity of conversing with a gentleman who was for some years manager of one of the branches of the photographic establishment of Fredericks and Co., one of the best reputed houses in New York. This gentleman, Mr. Cohner, is now principal of a large establishment in Havannah. He informed us that for the last three years, long before the reputed secret was published, he had practised the fuming system with all his prints, and was so thoroughly convinced of its advantages that nothing could induce him to give it up. To him it appeared that it was just the one thing required to give perfect excellence to many of the prints he saw in this country and in the cities of Europe he had recently visited.

The only mode in which he could explain to himself the apparent indifference on the subject which had been manifested in this country was by attributing it to some misapprehension of the real claims of the process which had, he thought, been a little mis-stated and misunderstood. He put forth but trifling claims for it on the score of superior sensitiveness or greater economy. It was on the higher quality of the result he insisted. The prints were out of all proportion richer, deeper, and more brilliant, and possessed perfect immunity in all cases from mealiness. The shadows of the prints produced upon fumed paper possess, he states, a velvety depth altogether unattainable by any other means. And the extra labour and trouble when once the arrangements were made and the system brought into working order was altogether insignificant. Neither were the fumes of ammonia in the printing-room found at all injurious, although at the outset formidable annoyance had been anticipated.

The system of printing adopted was as follows:—The fuming box consisted of a large deal chest, which had originally been a packing case, of about thirty inches or three feet square. This was papered at all the cracks and joints to make it tolerably air-tight. A saucer containing about an ounce of strong liquid ammonia, covered lightly with cotton wool to diffuse the fumes, was placed at the bottom. A

dozen whole sheets of paper were suspended upon wooden rods above the ammonia, and the lid was then closed for about fifteen minutes. The nitrate bath contained sixty grains to the ounce; half of it was converted into ammonio-nitrate of silver by the ordinary method of precipitating with ammonia and then adding ammonia until the precipitate was redissolved. This ammonio-nitrate solution was then added to the other half of ordinary nitrate solution. A slight precipitate of oxide of silver was thus caused, which was allowed to subside and remain in the bottle. The paper was excited on this bath for just one minute. When dry, but not until quite dry, it was fumed as we have described. The effect of the fuming is to make the paper rapidly discolour, sometimes reaching a cream tint during the operation and a buff colour in an hour or two; but this discoloration does not, in the slightest degree, affect the purity of the finished print.

The exposure may possibly be a trifle shorter, Mr. Cohner observed, than by the ordinary method, but not sufficiently so to have excited his attention. The appearance of the print is, however, very different. Even with thin, poor negatives, the shadows rapidly bronze and acquire a depth of reduction without overdoing the lights, which ensures richness and vigour in the finished print. The printing in his establishment is carried tolerably deep, and the prints are well washed before toning.

The toning both is made as follows:—

Chloride of gold	1 grain.
Chloride of lime	1 "
Water	4 ounces.

This solution is allowed to stand twenty-four hours, and is then ready for use. The tones are rich and deep, but warm, and, for the majority of subjects, have the most satisfactory effect; but where pure black tones are required, half a grain of nitrate of uranium is added for each grain of chloride of gold. With this addition the most perfect black tones, like those of engraving, are secured. The fixing and washing are conducted in the usual manner.

It happened unfortunately that we were not at home when Mr. Cohner first called upon us, introduced by Mr. Anthony, of New York. He then proceeded to visit various cities in continental Europe, and before he returned to London, on his way back to Havannah, he had parted with every specimen of American photography which he had brought over, so that we cannot add to his description of these results the indorsement derived from inspection. But we are familiar with the excellent printing of many American photographers; and we have seen prints from Messrs. Fredericks, where the same system is pursued, of unusual excellence. The fact, moreover, that this fuming system is used in large commercial establishments, amongst a people so pre-eminently practical and labour-saving as the Americans, speaks volumes in its favour. They are especially free from the fetters of custom or habit, nothing is likely to obtain general practice amongst them, unless it be followed by essentially and

tangibly beneficial results. And for these and similar reasons we are led to suspect that the system in question has not yet received in this country a sufficiently fair trial, and that it may yet repay further, fuller, and more careful experiments.

The specimens of printing we frequently see are far from being perfectly satisfactory, especially when the negatives are thin or veiled. And as imperfect negatives must often be printed, a method which will ensure more brilliant prints is of great importance. As a correspondent remarked in a recent letter, good negatives will yield good prints by almost any process, what is required is a method of obtaining moderately fine prints from indifferent negatives. For this purpose, at least, the fuming is worth trying.

ASSAULTS IN PHOTOGRAPHIC STUDIOS.

PHOTOGRAPHY is in some respects unfortunate. Because black sheep have occasionally been detected, there are some people who think themselves justified in referring to the whole flock as tainted. In times, we trust entirely gone by, when the cheap dens were much more common than they are now, quarrels about the price of the shabby production were not quite uncommon, and occasionally quarrels led to assaults. We are glad to believe that the assaults, and the occasions which led to them, are now much less common than they were, if they are not entirely removed. But with indiscriminating people the stigma still sticks, and it is felt to be a safe thing to sneer at photographers and photographic studios. A letter, which appeared in the *Daily Telegraph* a few days ago, is an illustration of this. It is as follows:—

"PHOTOGRAPHIC ROOMS.

"TO THE EDITOR OF THE 'DAILY TELEGRAPH.'

"SIR,—The press will do well to caution ladies against going alone to a photographic studio, as it is called. A young relative of mine, who has considerable personal attractions, went a few days since, without any attendant, to a photographer in the Western Central district, to have her portrait taken, and when she entered the room the photographer sent his son out of it, locked the door, and, without saying a word to the young lady in question, kissed her, and attempted to take her to a sofa. She, however, cried out, and told him that she would scream 'Murder,' if he did not desist. This, as his wife was within hearing, alarmed him, and he unlocked the door, out of which my young relative immediately rushed.—I am, sir, yours, &c.,
"SENEX.

"September 18."

Now, assuming this story to be in all particulars true and unexaggerated, it should surely have occurred to "Senex," if age had brought the discretion which belongs to it, that it was a case for the police-court, where suitable punishment would have reached the individual offender, rather than for conveying a general inuendo against an entire profession. A teacher of writing was recently severely punished for taking a similar liberty with a pupil. But is it fair?—is it reasonable?—is it to be tolerated?—that because a profession has unfortunately been disgraced by one scoundrel, that the stigma is to rest on all, and a general caution should be issued warning ladies against trusting themselves in their power? Ladies have been swindled occasionally in a draper's shop. Acting on the advice of "Senex," they should never trust themselves in a draper's establishment without an efficient guard; and, especially, should they never trust themselves alone in the establishment of a dentist, a teacher of music, of drawing, of writing, or of any other art, simply because in these professions there may have been blackguards, who have forgotten that the more unprotected a woman, the greater demands she possesses upon chivalry. Photographers know well, sometimes to their serious cost in wasted time, that ladies generally do visit

their establishments in companies, and it is sometimes absolutely necessary to place a prohibition upon any one but the sitter entering the studio, in order to avoid interference or distraction of attention. In other cases it will happen that if a lady may not go without company, she cannot go at the time which suits her at all. In these and a variety of other cases the unreasonable and sweeping advice of "Senex" would, if followed, be very injurious.

The unfairness of the general stigma has been felt by many photographers, and finds expression in the following, which appeared in the *Telegraph* a day or two afterwards:—

"TO THE EDITOR OF THE 'DAILY TELEGRAPH.'

"SIR,—We think it only fair towards respectable photographic establishments that your correspondent 'Senex' should state the exact locality of the place where his relative was treated so disgracefully. To only mention the postal district leaves a number of other establishments open to suspicion; and in fairness to ourselves and the public, we have, we think, a right to demand that your correspondent should be explicit, and state publicly the address, if not the name, of the offending person.—We are, sir, yours, &c.,

"THE PROPRIETORS OF VARIOUS PHOTOGRAPHIC ESTABLISHMENTS IN LONDON.

"September 21."

"Senex" as yet has made no sign in answer to this letter. Should he fail to give the due publicity to the name of the offender, or point out his residence, the legitimate conclusion will be that he has given publicity to an exaggerated if not a fabricated and euluminous statement.

MR. BLANCHARD'S MANIPULATING BOX.

We have frequently been asked by readers to describe the tents or portable laboratories used by different professional photographers who have distinguished themselves by open-air photography. These differ according to the tastes and necessities of the operators. Mr. Bedford has a carriage fitted up as a dark room. For London street work, Mr. Blanchard frequently uses a cab, its windows covered with yellow calico. Mr. Wilson uses a very primitive and simple tent. Except for London streets, Mr. Blanchard uses a dark-box, or manipulating chamber, which does not envelope the head, and the majority of his fine instantaneous pictures have been produced in it. Mr. Samuel Fry uses one of very similar construction. As Mr. Blanchard's box is especially distinguished by simplicity, portability, and convenience, we have asked him to describe it for the benefit of our readers. We may add that whilst Mr. Blanchard has not placed any prohibitions, by registration or otherwise, upon photographers making it for themselves, and by his description affords them every facility for doing so, for those who do not wish to take the trouble it may be interesting to know that it is manufactured for sale by Mr. C. E. Elliott, under Mr. Blanchard's instructions. Here is the description:—

"MY DEAR SIR.—In compliance with your request, I have sent you a description of my dark box, and trust it may prove of service to some of the readers of the *PHOTOGRAPHIC NEWS*. Some years ago I used to bag up my head when away from home, but too frequently I found myself quite abroad in my operations. Since, however, I employed my dark box I find my labours much simplified. It is quickly put up and taken down, and when packed is quite a compact affair, quite as easy to carry as a portmanteau. The bath, washing tray, tank, holding half a gallon of water, and into which all the chemicals necessary for a day's operations, snugly pack without fear of breakage, cloths, and box large enough to carry twenty-four plates $8\frac{1}{2} \times 6\frac{1}{2}$, all packed inside. Indeed, I carry everything except camera and legs, in the box. I have trudged many miles with the camera, strapped to the legs, slung across the shoulder, and the dark box like a portmanteau in the other

hand, for I always hold it a grand thing in out-door photography, as in matters political, to be independent of foreign aid.

"The box I regularly employ is 20 inches long, 7 inches broad when closed, and 14 inches high, outside measurement. It opens in the side, and is divided in the middle—one-half drops down and the other is raised up. The doors are held

in place by knee joints. When open for work the box forms a dark chamber 20 inches by 14 inches. A hood comes over the open part, in which are two sleeves for the arms. There is a window in the back, glazed with yellow glass, which slides open, and through which the plates and dark slides are passed. When not in use a shutter closes and effectually protects the yellow glass from injury. In the top lid is also a window similarly protected, through which the operator watches the development of the picture. The tank is placed on the top, with a pipe coming through the box, so that no room is taken up unnecessarily inside. The tray to catch the water during the operations of development and fixing, is a folding one, with a pipe going through the box to carry off the waste water clear of the feet of the manipulator. The bath is placed in one corner of the box, but facing the window. When developing, I stand the dark slide in front of the bath, so that no developing solution can by accident be splashed into it. I think this box will be found to be as portable and, at the same time, as convenient as anything yet described, for, when open for operations, it is just twice as large as when packed, and

when everything required for a day's operations is safely stowed away, the box is as easily carried in one hand as

a carpet-bag. I may add the box is now manufactured for sale by Mr. C. E. Elliott, and those who fear the trouble or risk of making one, can get it from him at a price as low as would be charged by any carpenter."

VALENTINE BLANCHARD.

THE MANUFACTURE OF PHOTOGRAPHIC COLLODION.*

BY W. L. NOVERRE.

HAVING prepared our pyroxylic by the formula given, we will next consider the chemicals required for making collodion from it, viz., the ether and alcohol in which it has to be dissolved, and the iodides and bromides which are to be mixed with the solution.

ALCOHOL.

There are two kinds of alcohol met with in commerce, pure and methylated; the latter is ordinary spirit with 10 per cent. of wood naphtha added to it, this is issued free of duty, being rendered unfit for human consumption by the addition of the wood spirit which communicates to it a very unpleasant taste and odour, but does not interfere with its employment for many chemical operations or in the arts, while it can be obtained at half the price of pure spirit. The strength of both kinds of alcohol varies according to the method of preparing them, it is convenient to have two kinds—rectified spirit, sp. gr. .820, and a stronger quality sp. gr. .796 to .800; by varying the proportions of these a spirit of any strength we require may be obtained. A few words may be said about the preparation of alcohol, that persons unable to purchase a suitable quality may know how to make it. Ordinary spirit of wine may be prepared by gently distilling brandy, rum, arrack, or other spirit in an ordinary still, stopping the operation when the spirit which comes over is found to be too much diluted with water, this can be ascertained by tasting it, or more accurately by taking its specific gravity; in order to obtain alcohol sp. gr. .820 from this spirit, it must be shaken up in a bottle with powdered carbonate of potash or pearl ash, thoroughly dried in an iron pan over the fire; when the salt has mixed thoroughly with the liquid, it may be put aside till the mixture of potash and water has subsided, when the alcohol

* Continued from p. 451.

may be drawn off, and the operation repeated with fresh potash till the salt can be shaken about in the liquid without being wetted, the spirit may then be distilled to free it from any impurities in the potash that may have dissolved in it. If it is intended to distil it off chloride of calcium or lime, this will not be requisite. To make alcohol sp. gr. '805, the last named spirit must be distilled at a gentle heat off fused chloride of calcium, six ounces of the salt being mixed with a quart of alcohol, sp. gr. '820, in a still; as soon as the chloride has dissolved, apply heat, and allow the spirit to distil over slowly. The first portions that come over will be the strongest; it will be safer to leave a few ounces in the still, as the last portions will be weak if the distillation is carried too far, it will also prevent the residue from setting in a hard mass at the bottom of the still; the residue may be poured out after the operation into a shallow iron pan, and evaporated to dryness over a fire, when it will be fit for a future operation. The specific gravity of absolute alcohol is '794, but it is seldom met with of this strength, being more generally '796; it may be made by distilling spirit, sp. gr. '820, with half its weight of quicklime. The lime is broken up small, and placed in a still with the spirit. It is then loosely corked, and left for two or three days, till the lime appears slaked; the alcohol is then distilled; a strong heat will be required towards the end of the operation. For distilling spirit off chloride of calcium or quicklime, an ordinary still would be unsuitable, as the joints do not fit sufficiently close. Philips's still, manufactured by Messrs. Jackson and Townson, is perfectly air-tight and admirably adapted for the purpose.

Many have objected to the use of methylated alcohol and ether in the manufacture of collodion. Amongst other objections, it has been urged that the bath will gradually become injured; there appear, however, no grounds for this idea. A bath which has been in constant use for more than a year, with collodion made from methylated spirits, is still in perfect working order: the quantity of ether and alcohol that has accumulated in it causes the film to dry rather quickly, and makes it rather difficult to get the developer evenly over the plate when it has been kept long between sensitizing and development; but it works cleanly, and free from spots. In order to be positive that the presence of methylated spirit in the bath had no effect on the sensitiveness of the plates, this bath has been tried side by side with a new bath prepared on purpose.

Collodion prepared from methylated spirits will, perhaps, decompose a little more rapidly after iodizing than that prepared with pure ether and alcohol. This is not shown by liberation of free iodine but by the collodion yielding rather a rotten film and an intense image. Much will, of course, depend on the nature of the iodide employed, the quantity of bromide, the purity of the pyroxyline, the age of the ether, and the temperature in which the collodion is kept. Collodion prepared with good methylated ether and alcohol, bromo-iodized with equal parts of iodide of ammonium and cadmium, with half a grain of bromide per ounce, has been kept without deterioration for six months during the summer, and would probably keep much longer. Methylated alcohol is sold of three kinds—the ordinary spirit, sp. gr. '820; the so-called absolute having a sp. gr. '796; and a third kind, which is allowed to be sold by unlicensed dealers, containing a small quantity of shellac, being intended for varnishes and burning in lamps, &c., it is quite unsuited for photographic purposes. The presence of the impurity may be detected by adding a few drops of water to the spirit, which renders it milky by the separation of the lac, which is insoluble in water. Methylated spirit which has been long kept acquires a much stronger smell than that freshly distilled. The specific gravity of methylated spirits is deceptive on account of the wood spirit it contains, the specific gravity of that substance being '798.

ETHER.

There are two kinds of ether, pure and methylated. The

specific gravity of ether prepared from methylated spirit is less than that of pure ether prepared by a similar process. The specific gravity of ordinary pure ether is '750, and of methylated '730; a stronger kind of pure ether can be obtained, having a specific gravity '725. Either of these are suitable for collodion, but care should be taken to obtain a sample by a good maker, as, if the process is not conducted with proper care, the ether is liable to be contaminated with impurities, which injure the keeping properties of the collodion. The remarks made on the employment of methylated alcohol in collodion apply equally to the use of methylated ether. Ether is an unstable substance, by keeping and by exposure to the air or to light it becomes ozonized, in which state it liberates iodine from iodized collodion. Ether from methylated spirit is more unstable than pure ether, owing to the presence of methylic ether, which absorbs oxygen more readily; it is, probably, this substance that makes collodion prepared with methylated less stable than that made with pure ether, and it is not unlikely that collodion made from pure ether and methylated alcohol would be quite as stable as that prepared with pure alcohol and ether: those persons who consider methylated spirits unfit for making collodion have, probably, used a greater proportion of ether than alcohol in their experiments, thus introducing a larger quantity of the objectionable substance into the collodion. In the experiments described in this paper the proportion of ether has never been more than half that of the alcohol. The fumes of ether must on no account be allowed to come near the flame of a candle, as they are highly inflammable; and the distillation of ether should not be attempted, except with proper apparatus, and by a person accustomed to chemical operations, as serious accidents are likely to result.

Alcohol and ether, pure and methylated, of the specific gravities above named, as well as the acids of proper strength, together with the other chemical apparatus and chemicals required, may be obtained of Messrs. Jackson and Townson, 89, Bishopsgate Street Within.

(To be continued.)

JOTTINGS FROM THE NOTE-BOOK OF A "PHOTOGRAPHER'S ASSISTANT."

No. II.

PRINTING AND TONING DIFFICULTIES.

IS entering once more on the difficulties which characterise our printing operations, anxiety to throw a little additional light on that perplexing subject must plead an excuse for our temerity in venturing again on what may be deemed a threadbare topic. We admit much has been written, and manifold have been the arguments advanced in favour of this or that system proposed, but the humorously poetical laments of Cha-meal-eon, the doleful complaining of others, and the plaintive appeals made by the many—all these prove that we are nearly as far off from real success as ever. True it is, in the hands of the few certain formulas have yielded results that seem to approach perfection; but whilst the few have succeeded, others with apparently the same description of material, and in reality an equal amount of manipulative skill, they, in practising on the same formulas, have met with temper-trying failures, giving room to those who by chance have succeeded to plume themselves on their superior abilities. Now, we venture unreservedly to assert that if each party exchanged materials success and failure would change sides at the same time, because the formulas are founded on the results of experiments entered into with chemical compounds whose accidental properties are so variable that no two samples from the hands of different makers can be declared identical in their constitution. Now, if our printing operations were conducted on principles based on well-defined and thoroughly understood laws, the control over accidental disturbances which interfere with the proper working of the solutions might easily be

attained, as one or two experiments would be sufficient to determine their character. As an illustration, we may point to practical mechanics; this science, theoretically speaking, admits of no influence but which friction and other causes are known to exercise, because, being accidental, their retarding power can only be determined by experiment. As with mechanics, so in photographic operations, chemical laws are as undeviating as those that govern the mechanical powers, and in a theoretical view the same rule which applies to foreign causes may be observed; but in practice, if results are rendered unsatisfactory by the accidental elements set at liberty when the compounds are subjected to the solvent influence of water, then carefully conducted experiment, aided by intelligent observation, must determine the character of the interfering agent; but if the nature of that which is unchangeable is not understood, any attempts we may make to improve matters must of necessity be empirical, and chance must govern results, and to this blind reliance on chance are we indebted for the thousand and one perplexities that retard the progress of our art.

Without further remarks by way of preface, we now commence the subject before us, which we enter upon with a sincere hope that the suggestions and arguments we intend offering will prove a stepping stone, by the aid of which all hitherto unsuccessful ones may be enabled to surmount their difficulties. The subject will be discussed in the following order:—

1. The conditions required in photographic papers.
2. The unscientific and expensively wasteful means adopted for producing what is erroneously termed coagulation of the albumen.
3. The influence exercised by the presence of free acid in our toning solutions.

Our knowledge of the conditions required in photographic papers appears to have remained just where Mr. Hardwich left it. Had that gentleman continued with us, his rare penetrative genius would long ere this have devised means to banish meanness for ever; but photographers, generally, regard printing operations as purely mechanical, and, as such, they entrust this department to assistants, who come in for a full allowance of grumbling when failures occur; whilst the last-named class find a ready excuse by abusing the paper, which, like the kitchen cat, is often blamed for faults that belong to the fault finder. In the year 1861 an attempt was made to induce the paper manufacturers to undertake a series of experiments in order that a better material might be produced. The results of their labours is briefly told in the NEWS ALMANAC for 1862. "They have turned out miserable failures." Were they to blame for their ill success? Not at all. We set men to work to provide remedies, without affording any reliable information respecting the true cause of the evil which was erroneously attributed to the sizing employed in the manufacture of paper, and a lot of scientific nonsense about saponified size and acid size was produced to guide them in their researches. But, as size of some sort is absolutely necessary, and none better suited for the purpose could be obtained, the matter was allowed to drop, whilst grumbling continued with unabated vigour. If as much time had been employed in patient observation as has been consumed in finding fault the difficulty must long since have passed away, for it would have been discovered that the sizing which paper contains exercises no influence whatever in the production of meanness. Incorporated with the fibres, it binds them together, thus modifying the absorptive tendencies which render papers unfit for writing or photographic purposes. In plain salted paper printing, or with paper slightly albumenized, the size, doubtless, contributes its share of influence, because, under those conditions, the silver, obeying the laws of chemical affinity, unites itself to the organic matter—access to which is readily gained by the open pores—but the fact that plain or very slightly albumenized papers are not liable to meanness proves that the sizing has no part in the production of the evil. On the contrary, for

if the silver, under all circumstances, could associate itself with the sized fibres of the paper, and when exposed to light reduction was effected to the same depth, no amount of bleaching would produce meanness. When one layer was removed, another of the same kind and colour would offer itself to the biting influence of the bleaching agent, and this reduction might continue until the albumen coating was entirely eaten away, and still those white, grain-like spots would not make their appearance until the fibre itself was divided, except, indeed, the oft-repeated theory be correct, which accounts for meanness by attributing its cause to free chlorine entering into combination with the reduced silver, thus forming anew a white chloride of the metal. But this explanation, reasonable as it may appear, cannot be supported by evidence, as the following remark will prove. If meanness owed its existence to this cause, then would the disease be discovered in every print that had been subjected to toning action, no matter whether printed on plain or any other kind of paper; in a word, where reduced silver is found there would the white chloride be formed, because no gold toning solution exists that is free from liberated chlorine, that is to say, if the bath is in working order; but this topic will be more fully entered into in our "Jottings on Toning." Then admitting that our views on the cause of meanness are correct, what are the required conditions to produce even toning? Why, simply a surface that is perfectly smooth and evenly coated with pure albumen, so that the reduced silver may be of an equal thickness throughout, for the impermeable properties possessed by albumen (in our opinion) do no admit the decomposed nitrate salt to any more than an infinitesimal depth, but slight as the distance might be, the prominent fibres of the paper prevent the existence of the necessary conditions, except the bleaching power is reduced to the smallest compass. Mr. Sutton's india-rubber paper is the nearest approach to perfection we have yet seen, but there has been a mistake made in the albumenizing that renders much of it useless when exposed to ordinary treatment. The nature of the error will be pointed out in our next paper. We cannot conclude the present jotting without giving expression to a belief that if paper manufacturers would accept our suggestion as a basis for further experiment their well-known skill would soon enable them to place into the hands of photographers an article which would rid their vocabulary of the dreaded term meanness; and whilst conferring a boon on society generally, their own exchequer would be largely benefited by the introduced improvement. The views alluded to were fully explained in our paper, headed "An Attempt to Produce Even Toning."

PHOTO-BLOCK PRINTING.

No I.

BY JOSEPH LEWIS.

THE process of obtaining a raised printing surface by means of a coating of bichromate of potash and gelatine has now been several years before the public, but we have not had the pleasure to know of its complete success. My experience in the matter has taught me in this, as in other kindred processes, the more direct we are in our manipulations the better will be the result. Herr P. Pretch and others agree that the coating of gelatine should be quite dry and hard, and that the swelling up of the impression should be accomplished *after* exposure, and in this, I think, lies a cause of imperfect results. I use a mixture of gelatine and glycerine with the bichromate, similar to that described in my second article on photolithography, page 414. I do not allow the film to become completely dry, therefore the action of the light takes place at once and the resultant effect may be watched by having the negative suitably hinged so as to raise it up occasionally and shut it down with accuracy. I can thereby time the exposure until the lines are sunk low enough to yield an electrotype fit for printing. The action

of the light is of a twofold nature; while it renders the film waterproof it exercises the valuable property of contracting or shrinking the film in the most complete manner, so that on removal of the sensitive film from under the negative it is ready for casting from at once, and the sooner it is done the better.

A PHOTOGRAPHIC TROUBLE.

BY C. W. HULL.*

Why is it, good Mr. Editor, that all the photos in the land sit love mystery; so seek after complications which they do not understand, rather than aim to reduce our beautiful science (though some call it an art) to some simple and uniform practice? Mankind is naturally prone to mystify and make much out of little, to pretend to great knowledge and excellence through roundabout paths, believing as a rule that they excel just in proportion to their ability to confuse.

You will wonder why this homily is read to photographers; but you would not, had you been present at a late meeting of the Photographical Society and had listened to the thousand and one different ways suggested to produce good prints. One person said good prints could only be made by floating on a *hundred-grain bath for five minutes*; another thought forty grains was enough, and float two minutes, but he would add a *little nitric acid*, and a *little ammonia*, quantity not important, so that it was *not too much*. Another had worked to his satisfaction by dissolving oxide of silver in nitrate of ammonia, and he had to use only five grains to the ounce. Another did not believe any such solution could be made, and so on.

I beg to inquire if the heathens had any gods of Photography; if so, let us implore them to step in and save us or we'll all go mad. So much for the silver bath; now how to tone.

It is scarce worth while to speak of it, for no conclusion was arrived at. One could not get tones unless he used nitrate of uranium; another must have the chloride; another wanted acetate of soda, and another a saturated solution of phosphate of soda; and another a pinch of salt—a little citric acid—a little chloride of lime—and how many more salts and chlorides your correspondent knows not. He has a good memory for most things, but it is not equal to photographic formulae.

After everybody had had his "say" but to disagree, a few prints, the production of one of our best amateurs, Mr. J. M. Masterton, were shown, and all agreed that nothing was wanting in tone or finish to make them equal to the best; and better still, they were produced by a simple process familiar to all. No legerdemain, no half dozen ingredients in bath to sensitize, tone or fix. Paper floated on plain bath of nitrate of silver, 70 to 80 grains, fumed by the very much abused ammonia, which confuses so many, toned in gold made faintly alkaline with carbonate of soda, and fixed in plain hypo. If this was not a "settler" to complicated processes, it should have been; but I fear it was not.

Photographers should bear in mind one thing, and from it they can learn if they will, why it is that one man's prints so far excel another's. It is that one makes good clear and brilliant negatives, while another has thin and foggy ones. The last named has bad prints;—lays his difficulty on his printing experiments, gets "no better fast," and concludes the first has some great secret.

The best prints come only from him who makes the best negatives. This is the corner stone of photography, and the man who so works will succeed and never till he does.

THE ECONOMY OF TONING.

BY J. H. LAWYER.†

In using the gold toning bath much economy may be realised in its preparation. It is evident to the writer, from experiments recently made, that no part of the gold used in toning is exhausted, except what mechanically adheres to the prints on their removal from the toning bath; it follows that the quantity of solution used is very important as regards the economy of the operation. It is evident to the writer that the gold bath will tone prints so long as the

action of alkaline soda continues upon auro-chloride of gold, and that when the gold solution becomes thoroughly alkaline the toning properties of the bath cease. Therefore to tone two hundred prints it is only necessary to make up a bath of ten ounces to perform the work if only sufficient carbonate be added to tone moderately at first, and prolong the action of the bath until all the prints can be immersed in it.

The action of a small quantity of solution properly mixed may be as prolonged as that of a larger quantity. In fact, no amount of solution will tone longer or more than another, except as the action of the soda upon the gold is prolonged or hastened. When that action ceases the bath will tone no more in its present state, and if it be immediately precipitated, it will be found to have lost none of its gold except what adheres mechanically to the prints in removing them from the bath. Seven-eighths of the gold originally used will be still found in the solution, and may be precipitated from it by means of sulphate of iron or sulphuret of potash.

A SHORT LESSON IN PHOTOGRAPHY.—No. 15.*

In my last lesson I gave you the method pursued in the preparation of sensitized albumen plates for negatives, and observed, I believe, that some of the finest stereographs in existence were made on such plates. These transparent positives by Ferrier, of scenery in Egypt and elsewhere, are unsurpassed for softness, sharpness, transparency, and richness of tone. It seems to me to be a pity that more attention has not been bestowed on manipulations with albumen, so as to obtain a more sensitive surface; for the albumen film possesses some advantages over the collodion film for photographic purposes: it is much less destructible, because when dry it is very hard; it is very thin and transparent and can scarcely be distinguished from the glass on which it has indurated; it requires no varnish; it mixes freely with the iodides and bromides; it is not subject to that peculiar decomposition to which pyroxyline is prone. Its disadvantages are the difficulty of obtaining a uniform film and of drying it quickly, also of operating with it in the *wet state*. If means can be devised to use it in the latter condition I think it will be *superior* to collodion.

I will now proceed to another process, called the Taupenet process, from its having been originally proposed by this French gentleman. This design was to combine the advantages of these two ingredients, albumen and collodion. The collodion film on the glass is a much better receptacle of the albumen than the glass itself; but the operation is somewhat circuitous, inasmuch as the plate is sensitized twice. Other methods have since been devised in which the collodio-albumen film requires but one sensitization. Some of these are found to be very effectual dry processes.

Preparation of the Glass Plates.

These are first immersed for a number of hours in the following solution:—

Salts of tartar	1 ounce
Rain water	16 ounces.

If the plates have been already employed before, soak them in water and remove the collodion film with a piece of rag. The alkaline solution can be used several times. As soon as the plates are removed from this solution, pass them through water several times and then clean and polish them in the vice by means of alcohol and rotten stone as directed in some of my preceding instructions. Immediately before the collodion is flowed upon the plate, it is dusted with a silk cloth and then with a broad camel's-hair pencil. A collodion that flows well and one that adheres forcibly to the glass is to be preferred.

* Amateur Photographic Print.

† The American Journal of Photography.

* From Humphrey's Journal.

Formula for the Collodion.

Concentrated ether	12 ounces
Alcohol	3 ounces
Pyroxyline	1 drachm
Iodide of ammonium	1 drachm
Bromide of ammonium	15 grains.

The collodion, containing quite an excess of ether which is very volatile, has to be poured over the plate with great dexterity. It is very fluid, and admits of this dexterity. The plate is then, as soon as the film has sufficiently congealed, immersed in the ordinary nitrate of silver bath containing about 35 grains of the nitrate to the ounce of distilled water. It is left in this bath for four or five minutes, and then taken out and allowed to drain. After this proceeding the plate is immersed in a dish of rain water and well washed by agitation, or it may be washed at the tap by the ordinary method, and then flowed with distilled water several times and again allowed to drain. It is next flowed, whilst still moist, with the following albuminous preparation :

The white of eggs (free from germs and yolk)	12 ounces
Distilled water	2 ounces
Iodide of ammonium	44 grains
Bromide of ammonium	16 grains
Ammonia	1 ounce
White sugar	2 drachms.

These ingredients are intimately mixed by an egg-beater until the mass is reduced to froth. They are then allowed to subside for a day or two. The clean part is separated by decantation or by a syringe from the residue below and from the indurated scum on its surface above. With this clear solution flow the still moist plate as you would with collodion almost. Holding the plate by the left hand nearer corner between the thumb and the first finger, pour the albumen on the right hand further corner; then, inclining the plate, let the albumen flow to the left hand further corner. Now allow the whole body of the albumen to flow down in one mass, driving the water before it until it arrives at the nearest edge. Inclining the right hand nearest corner, allow the water to flow off together with the excess of surplus of the albumen into a separate receiver. Now raise the nearest edge of the plate and let the surplus proceed back again to its place of starting, and once more to the nearest right hand corner, when all excess is allowed to flow off. The plates are then reared away on one corner to dry. In this state the film is not sensitive, and consequently the plates so far can be prepared beforehand and preserved until wanted.

Sensitizing of the Taupenot Plates.

The plates are immersed in this bath with great care and dexterity in order to avoid all lines of stoppage, &c. In thirty seconds the film will be sufficiently sensitized. The plate is then taken out and plunged into a dish of water, moved about in this, then transferred to another, allowed to drain, finally flowed two or three times with distilled water and put away to dry in a perfectly dry place.

In this condition the film is much more sensitive to light than albumen alone, although it is less so than collodion. The plates can be preserved sensitive for several months, but the sensitiveness gradually deteriorates by age.

Exposure.

With a portrait combination an exposure of two or three seconds will be found to be sufficient to receive a good impression of an object well illumined by the sun, and as many minutes will suffice with a single lens.

Development of the Image.

The developing solution is composed as follows :—

Distilled water	12 ounces
Gallie acid	18 grains
Pyrogallie acid	6 grains
Alcohol	2 drachms
Acetic acid	½ drachm.

To every three ounces of this solution add a solution of nitrate of silver when about to use it. A larger proportion of pyrogallie acid will increase the intensity of the blacks; and, where the time of exposure has been too long, the gallic acid may be diminished and the acetic acid increased. The horizontal bath is preferable for this sort of development. The plate, first dipped in water, is then lowered dexterously, with the collodio-albumen surface downwards, into the solution; and the upper end is allowed to rest on a piece of glass or porcelain to prevent the film from coming in contact with the bottom of the vessel.

The plate is raised from time to time to watch the progress of the development, which may occupy from ten minutes to twenty-four hours. When the shades are intense enough, the plate is taken out, well washed, and then immersed in the fixing solution.

Fixation of the Taupenot Plates.

Hyposulphite of soda	1 ounce
Water	20 ounces.

Even a weaker solution will frequently be all that is required. The soluble iodides being removed, the plates are taken out and thoroughly washed as usual.

Modified Albumen Process. By James Larpey.

Let the plates be coated with any collodion, iodized or non-iodized, and afterwards well washed.

Now flow them with the albumenizing solution, which is made as follows :—

Formula for Iodized Albumen.

Albumen	10 ounces
Iodide of ammonium	50 grains
Bromide of potassium	12 grains
Water	2½ ounces.

The mode of flowing is the same as already described for the Taupenot process. After draining, dry as before indicated.

Sensitizing Solution.

Nitrate of silver	60 grains
Acetic acid	60 minims (1 drachm)
Water	1 ounce.

The time required will be thirty seconds or thereabouts; remove from the bath and wash thoroughly.

Exposure.

This preparation requires about twice as long an exposure as wet collodion.

Developer.

Take a saturated solution of gallic acid and a few drops of a solution of nitrate of silver (fifty grains to the ounce of water). By varying the quantity of nitrate of silver any kind of tone can be got. A small quantity yields brown tones; a larger quantity black tones.

Fixing.

Wash thoroughly, and then fix in the ordinary solution of hyposulphite of soda; finally wash and dry.

The collodion film in this process facilitates the flowing of the albumen, which besides dries much quicker. Its keeping properties are very good.

HINTS ON SUCCESS AND FAILURE IN PRINTING.

[MESSRS. LAMPREY, TIBBITTS, AND Co., of Paternoster Row, have recently issued a very useful pamphlet, entitled "Toning Formulae, and Instructions for Printing," &c. It is intended for especial use with their albumenized papers, but it contains a mass of valuable and trustworthy practical information on the general subject of printing and toning. We advise our readers to procure it. The following pithy summary is extracted from it.]

As all photographers know, one operator will succeed and another will fail, even with precisely the same materials and nominally the same formulæ. We cannot by the use of any

materials or formulæ *guarantee* success in all hands; but we can supply such materials and such recipes as *ought to succeed*, and we can point out some of the causes of failure.

WEAK PRINTS.—The primary cause of weak, feeble, poor prints, is the use of a thin or fogged negative. Without a good negative, it is impossible to obtain good prints. If the negative be good and the prints poor, it may arise from several causes—the nitrate bath being too weak or too acid; the paper not floated long enough or too long; not being sufficiently printed; being over-toned, left too long in the fixing bath, or in the first washing water after fixing. A marbled or mottled effect is often due to the use of a weak silver bath.

MEALINESS.—This is a term used to designate a fact with which many photographers are familiar. It consists in a granular mottled effect of grey and red spots on the surface of the print. It most commonly occurs where the negative used is thin, and does not permit very deep printing. It sometimes proceeds from the use of a very acid printing bath; sometimes from using a toning bath when too recently mixed, or containing free acid, or from using a lime bath containing too much chloride of lime. The best remedy, when the tendency exists, is slow toning; an old acetate bath has the least tendency to produce it. In some cases submitting the print, prior to toning, to a bath of acetate of soda, without gold, is found to check the tendency to mealiness.

RAPID DISCOLOURING OF THE EXCITED PAPER.—The use of an alkali nitrate bath, or of a bath containing acetic acid, will cause this, or keeping the bath in a warm and damp place; and the fumes of ammonia, hydrogen, gas, &c. After exciting, the paper should be dried in a warm place, and then kept in a cool dry one, and of course quite dark. Changing the prints in the frames, or examining the progress of the print and toning or fixing in daylight, are frequent causes of dull, degraded whites. The paper being kept too long between exciting and finishing the picture, produces a similar effect.

IRREGULAR BRONZED MARKS.—Impurities on the surface of the sensitizing solution.

YELLOW MOTTLED STAINS IN THE PRINT arise from using an old or weak hypo bath, or allowing the prints to stick together whilst fixing.

BROWN AND METALLIC STAINS often arise from handling the prints before fixing with fingers which have touched hyposulphite of soda.

HARD PRINTS WANTING IN HALF TONE, when not the fault of the negative, may arise from using the silver bath too strong.

SPECKS AND MARKS OF VARIOUS KINDS often arise from dust or marks at the back of the negative, or on the glass of the printing frame.

RED CIRCULAR SPOTS.—Air bubbles under the print whilst toning.

PRINTS REFUSING TO TONE.—This will arise sometimes from allowing too long a time to elapse between exciting the paper and toning; or from the gold bath becoming inert or exhausted, in which case, add a little more fresh gold solution; or from putting the fingers into the gold solution after they have touched hyposulphite of soda, and so decomposing the bath. The use of old collodion baths for exciting hinders toning.

PRINT RED AFTER FIXING.—Under-toning.

PRINT HAS A COLD, ASHY, BLUE COLOUR, WHEN DRY.—Over-toning.

THE ALBUMEN LEAVING THE PAPER generally arises from the silver bath being too weak.

A BLOTTED AND BAD TINTED COLOUR sometimes arises from the washing before toning not having been carried far enough, and from the print having been washed in water containing lime.

DIRTY WHITES are often to be traced to the use of a fixing bath that has been employed before, or to a discoloured nitrate bath.

THE WHITES OF THE PRINT ARE NOT SUFFICIENTLY PURE, BUT GREY AND DIRTY.—This may arise from exposure to light, use of ammonio-nitrate of silver, in damp and warm weather; contact with ammonio-nitrate paper; use of damp flannel on the back of the paper, or of flannel impregnated by frequent use with ammonio-nitrate of silver; too much exposure to the heat of the sun.

The exciting, printing, toning, and fixing should, where it is possible, be done within one day; and the utmost care and cleanliness used throughout. The fixing bath should not be used twice, and should contain one ounce of hyposulphite of soda in five ounces of water.

Many defects and failures, not otherwise explicable, arise from the use of impure chemicals. It is, therefore, economical, both as regards time and money, to procure the very best that can be had, quite irrespective of the cost.

AN ARTIST IN TROUBLE.—HELP WANTED.— PINHOLES AND VARNISH.*

MR. EDITOR—You know it was the character of the old Jewish nation to be always leaning on their own right arm until they were well whipped by some nation whose right arm was stronger than theirs; well, so it is with me; I like, when I get into trouble, to work my way out of it, and heretofore I have always succeeded, thanks to those "useless" publications, the photographic journals; but this time I have broken down flat, flatter, flattest.

About a week ago I ran short of ether, so I tried some from a drug store, and it failed, then I borrowed some, but from some cause the cotton would not settle in it although in former cases it settled all right, and the same ether gave my neighbour good, clear collodion. I take pains to procure good chemicals (iodide and bromide of ammonium and cotton), he uses whatever his stock dealer happens to send him—of course this collodion would not work, so as I had just received a fresh supply of ether, I made a fresh lot of collodion that looked beautiful, and here began my real trouble. I coated a plate, and it produced a very fine negative, and I thought my trouble all over; but alas! for human foresight; my second and third came out all right, the fourth showed pinholes which increased in quantity and quality until I had to stop altogether. Feigning business, I left my room and staid out until it was too late to work, and so saved my reputation for that day. At night I adopted my "never-failing" remedy of boiling my bath. As I expected, the first plate next morning showed all right again, but before half a dozen plates had been dipped, the pinholes were as numerous as ever. Thinking something was wrong with the bath dish (one of Stock's glass baths with rubber bottom and sides) I filtered a part into a porcelain bath and tried again: this helped, but did not cure, so I set the larger portion of the solution in the sun, where it stood from nine o'clock A.M. until dusk, when it was perfectly limpid, with a white deposit completely covering the bottom of the bottle; this I filtered clear, and as before obtained A 1 negatives at first, but the same trouble reappeared. I then reduced my solution with pure rain water until it was quite milky, and added silver to restore its strength to fifty grains per ounce. This proved an exact repetition of my former attempts, so that night I evaporated my solution to dryness, and then fused the silver. This just gave the same results, three or four fine negatives, and then gradually they went down to totally worthless. I now tried to see whether lengthening the time in the solution would change the effect, and *thought* the pinholes a trifle large. I then dipped my plate and took it out as soon as it ceased to show oily lines; what result say you? Not a pinhole but a splendid cedar swamp instead!

Here sickness gave me what a musical friend called a "three days rest." On resuming I thought I had fooled away time enough with the old solution, so I made a new one with Powers and Weightman's silver, and also a new batch of collodion made as follows:—

Ether	8 ounces
Alcohol	8 "
Iodide of ammonium	80 grains
Bromide "	32 "
Soluble cotton	130 "

This looked fine, and to my great pleasure my first negative was a splendid one, yet my old fate followed, and at night I could not make a negative of any value. I must own beaten, but unlike the champions of the "peculiar institution, I can't "skeddadle." Old dame Nature did not give me the

* *The American Journal of Photography.*

ability to flee either fast or far, so I assume the old salt's motto, "Never say die while there's a shot in the locker."

I hope long before the next Journal comes, to be all right again, but thinking that some of your friends might have travelled over similar ground, I would like to know how they got "out of the woods."

One of your Minor Correspondents is in trouble with his varnish, I cannot tell him the cause of the trouble, strictly speaking, but I can tell him both how to remedy it and how to avoid it. To remedy it, simply varnish the plate a second time, and (of course) dry it by a gentle heat. To prevent it, leave the varnish bottle open for a short time in a warm room, and there will be no trouble with opaque spots. I have taken negatives that were laid aside as worthless, and restored them so quickly that the owners would not believe I told the truth in regard to the means, until they had proved it.

I am sorry to see so little from the pens of our own artists, although I have no right to find fault, having left you entirely for a long while, but if I don't get a "situation" in Uncle Sam's shooting party now organizing for a grand hunt "among the pines," or elsewhere, as may be decided upon, I will try to send you an opinion; meanwhile I am, yours truly,

A. S.

Erie Pa., August 16th.

[Our friend A. S. in his troubles seems to have proceeded *secundem artem*. He ought to have been relieved of his difficulties; we never knew of similar cases where such remedies as he used did not prove effectual.

The common and well approved theory of pinholes, when they do not come from an imperfectly settled collodion, is that they originate from impurities of the bath. For a decisive test in a doubtful case, the collodion should be tried in another bath which has been proved to be in order. We have observed, however, where the pinholes are undoubtedly produced by deposition of iodo-nitrate or other foreign matters of the bath, that some unknown condition of the collodion has still much to do with the manner and amount of the deposition.

A good remedy, as we proved some years since, for pinholes, or a sandy appearance of the film, is to wash the plate after it comes out of the bath—this washing takes away the bath impurities; then before exposure, pour over the film a pure bath solution. This plan invariably secures a good clean negative. For regular working it would be advisable to have a water bath standing beside the silver bath, in which the sensitized plate should be rinsed, before washing under the tap (this may be omitted), for the purpose of saving the silver. The final silvering should be effected by pouring rather than dipping, as the latter takes twice as much silver as is really required. This plan would be economical of silver, while the photographic results would without doubt be nearly uniform notwithstanding the varying condition of the bath and the collodion.

Apròpos of saving silver in ordinary working, we suggest that just before developing, the plate be dipped in a water bath to remove the superfluous silver from the back; probably sufficient would remain in the film for development, and if not, let it be added as needed.

At a late meeting of the Photographical Society, President Draper recommended the plan of washing thoroughly before exposure, and of restoring the silver at the time of development.

These matters are full of interest and we hope to learn more from A. S. and others—En.]

Correspondence.

FOREIGN SCIENCE.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, September 30th, 1863.

An amateur photographer has communicated to the *Moniteur de la Photographie* an ingenious idea of the application of

the stereoscope to microscopic photography, which he has patented. He states that the employment of stereoscopic photographs occupying a very small surface permits of our giving to the stereoscope dimensions as limited as may be desired, and, consequently, render this instrument capable of assuming any form. Besides, the facility of combining a given number of pictures on a plate of small dimensions permits of a considerable reduction in the price of each proof.

The process of obtaining these stereoscopic proofs is very simple. A plate containing two stereoscopic pictures is placed in a frame, which maintains them in a fixed position. The back of this frame is covered with ground glass, which is lighted by the direct rays of the sun, by reflected light, or other means. I place in front of this frame a small camera with two objectives, and I take by the usual process, on albumen or collodion, two positives on glass.

The two reduced pictures thus obtained are exactly similar to those obtained by ordinary printing methods, and although they are ten, twenty, or even a hundred times smaller than the negative, the stereoscopic effect they produce is still the same if we view them with two lenses of sufficient magnifying power.

To judge of the stereoscopic effect, one single condition is indispensable. It is, that the two stereoscopic proofs be seen simultaneously by both eyes of the experimentalist. Hence it is evident that every imaginable form may be given to the stereoscope, for this condition is always easy to fulfil. I will describe a few of these forms.

1st. The simplest of all will be to place two stereoscopic proofs in two little lorgnettes, which may be connected by a chain. By taking one of these lorgnettes in each hand, and placing them both before the eyes at the same time, the picture will be seen in all its relief.

2nd. We can take any number of stereoscopic proofs on the same glass plate. Upon one part of this plate is placed the pictures A, B, C, D, E, etc., and on another the pictures AA, BB, CC, etc., which, to be viewed simultaneously, must have an interval between them corresponding to the distance between the eyes. To see all the images in succession, we make the glass plate containing them slide in front of two little microscopes suitably placed.

3rd. We can take a number of proofs arranged in a circle on two small discs of glass, mounted so as to partake of a rotary movement in the same plane. Two little fixed microscopes serve to view the stereoscopic proofs simultaneously.

The elements of this invention are not new. Microscopic photography is known to everybody, and so is stereoscopic photography. Nevertheless, the combination of these two things produces an artistic result which no one has hitherto foreseen, and for which I consider I am justly entitled to a patent.

It is not, I repeat, this form or that of stereoscope that I claim as my invention, but only the employment in the stereoscope of photographic proofs of very small dimensions which can be seen only by the aid of lenses more or less powerful.

Under the title of *photogenie*, Messrs. Susse frères have attempted to popularize photography after a fashion. Alongside of the outfit for *potichomanie* and *decalcomanie*, we now find an elegant ornamental box containing some small bottles, a miniature bath, a light frame, and a stock of engravings. With these appliances and a little practice, young amateurs can obtain photographic pictures with as much ease as they can sketch a flower or a figure. Everything is prepared for use, and there is no danger of the rosy fingers becoming stained. The albumenized paper is covered by means of a sponge dipped in the sensitizing solution, then placed in the frame under the engraving to be copied. After an exposure, which varies from fifteen minutes in the sun to an hour in the shade, the paper is immersed in water, then placed on a sheet of cardboard and covered with a solution of tannic acid; the proof is then washed and immersed in a solution

of sulphate of iron, washed again, dried, and varnished with gum-water. The resulting picture is permanent, for it is composed of tannate of iron. This process is quite as simple as *decalcomanie*, and will, doubtless, meet with an equal share of success.

Paper of very fine quality has for some time past been manufactured in Austria from the leaves of the *maize*, or Indian corn. Herr Auer, the director of the Imperial Printing Office, at Vienna, has issued a large album containing specimens of maize-paper of all kinds, thicknesses, and dimensions.

This plant, grown so extensively in the South of Europe, in the United States, and other parts of the world, furnishes one of the most important cereals that contribute to the nourishment of mankind. The leaves, for which no use had hitherto been found, except as fuel, contain three valuable elements: a textile material, a nutritive pulp, and a glutinous substance. The first is spun and woven; the second, which keeps fresh in the open air for several months, furnishes a nourishing and wholesome flour: all the filamentous and glutinous residues of the pulp resulting from the extraction and fabrication of the textile material are converted into paper. As may be perceived, nothing is lost. As for the paper, it has all the qualities of that made of rags: whiteness, suppleness, toughness, and transparency if required; it appears even more homogeneous. It will also be much cheaper, as soon as its manufacture is established on an extensive scale. Paper of this manufacture will, doubtless, prove interesting to photographers, as it will be free from many of the defects inherent to paper prepared from rags, as well as from its accidental impurities, so fruitful a source of spots.

THE TRIPLE V. THE GLOBE LENS.—ENGLISH PORTRAITURE, ETC.

MY DEAR SIR,—Mr. Waldack, on his return to this country, delivered to me your present of several beautiful photographs. The work of Dallmeyer's triplet, as compared with Harrison's globe lens, shows conclusively the superiority of the former, as compared with the latter, in the fact that the square picture cut from it includes more picture than the square picture cut from Harrison's, both being the same subject, and, I presume, both taken from the same spot.* I have a "six-inch globe lens that, so far from covering "a circle of light twelve inches in diameter," barely covers the corners of a $6\frac{1}{2} \times 8\frac{1}{2}$ plate. This lens is called "Six-inch focus," when in reality it is over seven inches. The focus measures six inches from the centre of the back lens, which projects a half-inch from the brass work. Measuring from the central stop to the ground glass it is more than seven inches. This practice of measuring focus from the back lens, without stating the length of the brass tube, is erroneous, and calculated to mislead the photographer.

I am using a lens made by Henry Fitz, of New York, which has a focus three-quarters of an inch longer than the globe, makes an image but very little larger, works much more rapidly, *completely* covers sharply an 8×10 plate, and costs much less than a six-inch globe. I think this lens resembles Dallmeyer's, as it seems to work out the corners of the picture in the same manner. I believe this Fitz lens can be used for in-door portraits as it works perfectly with a large opening, although I have not as yet fully tested it on this point. I will send you by next steamer a pair of prints made with the two lenses, so you can compare them. I still think there is a lack of uniformity in the manufacture of the globe lens, so if any of my Philadelphia friends "burst with indignation" because their "globes" work better than mine, then they or I will be open to conviction.

In conclusion, allow me to express my thanks for the photographs you sent me. I am at a loss which to admire most, but will submit them all at the next meeting of the

Photographical Society, in October, for comment. I think that the portrait of V. Blanchard cannot be excelled. I am told this was taken under a skylight, and the surroundings made up. If this be so, then we surrender the palm for making up in galleries, old marbles, shrubbery, &c., &c.† Then the portrait of Mr. Hardwich (where are his robes?) is universally admired. It is to be hung up in my house as a gem of art. The paper it is printed on is elegant in surface and finish. Whose is it? † Yours, respectfully,

F. F. THOMPSON.

New York, September 4th, 1863.

P.S. Since writing the above, yours of the 20th ult. has been received. I see you noticed the same peculiarity of working the corners with Dallmeyer's lens as I did. I apologise for the lack of regularity in my letters, but can promise better hereafter, as I have just now completed my new den, which has taken my time all summer, and can begin to do something again at pictures. I will secure to you the early reports of our Photographical Society when they again meet, and write anything of importance that may occur. I go into the country in a few days, and will write a line or two from our backwoods. Until then, good-bye.—Yours, F. F. T.

FORMIC ACID IN THE DEVELOPER.

SIR,—It is with considerable diffidence I again take up my pen to approach the editorial table, after the merciless way in which Lieut.-Col. Stuart Wortley has thought proper to cut up my unfortunate letter, "Formic Acid an Accelerator;" still, I do not think it would be doing justice to myself did I not say a few words in reply.

In the first place, Lieut.-Col. Stuart Wortley appears to have taken a wrong view of the whole affair. I was perfectly aware that Mr. Malone had stated "the avoidance of bromine salts in the collodion is absolutely essential to success." His opinion, I know, is endorsed by many other photographers, still I did not know of any law to prevent photographers trying for themselves whether pyrogallic and formic acid developer and bromo-iodized collodion were so inimical to success. Lieut.-Col. Stuart Wortley should bear in mind that I was not trying for instantaneous effects, but simply whether the pyrogallic and formic acid developer would give as good results with a fair exposure as the iron developer.

Again, I did *not* profess to make experiments on M. Claudet's ideas; I merely stated that I used a *developer* of pyrogallic and formic acids, *as recommended* by M. Claudet.

I did *not* "produce a better negative with the ordinary iron developer than with a developer containing pyrogallic and formic acids." The iron negative was flat compared with the other one, whose only fault was, the shadows were a very little too deep; the detail was equally good in both.

Since my former letter to you I have used the pyrogallic and formic acid developer in many instances with my bromo-iodized collodion, and have every reason to be pleased with the excellent results produced. I enclose you two cards from negatives developed by both methods; that is, one by pyro-formic acid, and the other by iron. They were taken in a moderately good light with a Jamin card lens, five inch focus, one inch stop; exposure for each negative, five seconds. It remains for you to say which is best.

It can but be a matter of indifference to me, so long as I can work successfully in the way laid down in my letter, who approves of it, or who does not. I only stated facts, and confess I was myself astonished, after being led to suppose that no one could succeed with bromo-iodized collodion and pyro-formic acid developer to get such good results.

As to the inutility of my experiments, many amateurs have an unconquerable aversion to iron development, conse-

* A portrait of Mr. Blanchard, by himself, in the costume of a Roman peasant, taken in the glass room he described in our pages. It is one of a series sent out by Mr. Blanchard, as illustrating the qualities of his collodion for iron development.

† A whole plate vignette portrait, by Mr. T. R. Williams, a charmingly perfect photograph and a fine likeness.

quently are precluded from using a bromo-iodizing collodion, but by a slight modification in the pyrogallie acid developer, as recommended in my letter, the beautiful results obtained by using a collodion containing bromide and iron development, can be got by them, with exactly the same manipulation as for simply iodized collodion and pyro development.

I cannot do better, in conclusion, than quote your excellent remarks, contained in page 444 of the News for the week ending Sept. 11th: "Whilst we never receive things as truths except on satisfactory evidence, we do not reject well authenticated statements as falsehoods simply because they appear improbable. Many things appear improbable simply because they belong to a range of facts which have not come within common experience."—I have the honour to be, Sir, your most obedient servant.

W. A. Moss, Sergt. A. H. C.

[Free discussion generally tends to the more perfect elucidation of any subject. We think it is probable, however, that Col. Stuart Wortley understood our correspondent to be experimenting with M. Claudet's process, and either mistaking or mis-stating the formula. The presence of a bromide has generally been regarded as injurious with pyrogallie acid development, and M. Claudet excludes it from his formula as we have repeatedly stated. That it is inimical, however, to perfect results, we are not so well assured as Mr. Malone appears to be. If Sergeant Moss is to blame for trying it with a pyrogallie solution and formic acid, we are not less so, for in two articles last June we stated that we obtained with bromo-iodized collodion and pyrogallie and formic acid development, results equal in rapidity and delicacy, but with a little more brilliancy, than with the same collodion and ordinary iron development. Sergeant Moss's pictures bear the same relations as our own. Some time ago Major Gordon presented some very fine and soft instantaneous pictures to the French Society, the peculiarity of which was that they were produced with a highly bromized collodion and pyrogallie acid development.—Ed.]

THE INVENTION OF THE TRIPLE LENS.

DEAR SIR,—Will you grant me space for a few lines in the PHOTOGRAPHIC NEWS, to answer some misstatements by Mr. Sutton in the *Photographic Journal* just issued.

A month must elapse before the error could be corrected in that journal, and for this reason I ask the use of your columns.

Mr. Sutton finds fault with the phraseology of the jurors in their Report of the Exhibition where they refer to the triple lens invented by me, and claims the origin of the Triple Lens for himself. Permit me to state that the Triple Lens invented by me and which has proved a success, has nothing in common with the "Symmetrical Triplet" invented by Mr. Sutton, and which proved a failure.

Domestic sorrows disincite me for entering further into the discussion at present, on a future occasion I shall have more to say on the subject; in the mean time I will conclude by confuting Mr. Sutton by his own words. On a recent occasion when I had to point out that my lens had been copied by another maker, Mr. Sutton remarked that "Mr. Dallmeyer ought to be pleased" to find that another maker had "verified by a series of experiments his own original results." (See *Photographic Notes*, May 1st, 1863). Yours truly,
J. H. DALLMEYER.

BAD GLASS PLATES.

DEAR SIR,—I send by this post a patent glass plate for your inspection. It is a fair sample of a lot of glasses I've just had down, every glass is covered with a peculiar mark which seems to me burnt in the glass. I've tried every scheme I know, but I can't get rid of them. When I unpacked them, there was a piece of paper between each to keep them from being scratched, the mark of which you will see is left, and defies all my efforts to get rid of it. Now,

can you, or any of your readers, inform me the cause of it, and the remedy? I shall be greatly obliged if you can. I've soaked them in strong nitric acid, cleaned them with a solution of tripoli, alcohol, salt and water, and put by for use. Before using, I've cleaned the plate with alcohol, yet in spite of all these precautions, I can't get rid of the marks. I had them of a first-rate London House and paid a long price for them, so they ought to be up to the mark. Hoping you will be kind enough to see to this and help me out of my trouble, I remain, yours respectfully,
R. T. BACK.

P. S.—If you can't find out the remedy, and tell me in the notice to correspondents, I should, if you have space enough, like you to publish my letter in the NEWS, as some of my brothers in distress might lend me a helping hand.

[The marking is similar to what we have met before. It has a smoky mottled effect, and defies all attempts to remove it. It does not always show when the picture is taken, but it does sometimes. We never met with it on patent plate, nor do we believe this to be patent plate. It looks like foreign polished sheet, of which one side only is polished. Perhaps some of our correspondents can supply more information.—Ed.]

EDEN'S MICROSCOPIC CAMERA.

SIR,—The camera you noticed and engraved in a recent number for taking micro-photographs, was made originally, four or five years ago, by a Mr. Potter (then resident in York, and now in my employ) for Mr. Willis, then of York, and now of Scarborough. Mr. Eden, about four years since, got Mr. Potter to make one for me, which I have still in my possession—Mr. Eden being then in my employ. The mirror has certainly been added since, as also the dark frame at the wide end, but these are the only improvements introduced by Mr. Eden, in every other respect it is like mine. I have written this to you because I think Mr. Potter should have the credit of its construction and arrangement, and as for the "patent," I should have no hesitation in infringing it if any person favoured me with an order, inasmuch as the real inventor would have to make them.—I remain, sir, yours truly,
J. CASCATELLI.

Manchester, September 8th, 1863.

[We must leave Mr. Eden to explain this charge of copying.—Ed.]

Photographic Notes and Queries.

IMAGE ON THE RETINA OF A DEAD EYE.

MR. WARNER presents his compliments to "Enquirer." He will, when he has leisure at his command, be happy to give his ideas upon the above subject. Also upon "non-actinic weather," upon which some curious facts are in his possession from all parts of the world. At present, his time is too much taken up with enlarging, printing, &c., &c., to enable him to give that attention to the subject which it justly demands.

Ross, September 18th, 1863.

GUTTA-PERCHA NEGATIVE TRANSFERS.

THE late ever to be commended Mr. Archer proposed this plan for the preservation of negatives, and it secures great economy of space to travellers. After the negative was completed he poured over it a solution of gutta-percha, and allowed it to dry. The plate was then placed in water and a gutta-percha negative or a negative on gutta-percha instead of glass was obtained from off the glass. The glass plate might then be cleaned and another negative taken on the same plate; the gutta-percha negative being easily preserved on being placed in the leaves of a book. These gutta-percha negatives bear very free handling; they can be printed from without any more, perhaps less, difficulty than any other kind of negative, and I have seen some still as perfect as when they were first made some years since. The invention was one of the greatest value to travellers, inasmuch as it saved the necessity of their carrying with them the contents of a glass shop. What have been the obstacles to the general adoption of this invention?

C. C.

[Except the trouble of removing the films, and a little tendency in the film and gutta percha to shrivel and get into creases, we have not heard of any disadvantage attending the process in question.—Ed.]

NITRATE OF SODA IN ALBUMENIZED PAPER.

SIR,—Perhaps the following suggestion may be of use to albumenizers. I have recently had some paper prepared for experiment as follows:—To each ounce of chlorodized albumen I added sixty grains of nitrate of soda. I find much more brilliant prints are the result. I have tried this paper on a weak bath, and find I get more brilliant results than with the same paper usually prepared without the nitrate, and sensitized on a 70-grain bath. A larger proportion of nitrate of soda may be more advantageous.—I remain, Sir, yours respectfully,

PUBLICOLO.

P.S.—I intend to have all my paper so prepared for the future.

Talk in the Studio.

MEDALS OF THE CORNWALL POLYTECHNIC SOCIETY.—We are glad to be able to record that the adjudicators of prizes at this society have awarded the first silver medal for the best photograph in the exhibition to Mr. H. P. Robison, of Leamington for his charming picture of "Stoucleigh Deer Park," and to Col. Stuart Wortley the medal for the best collection of photographs consisting of some magnificent instantaneous pictures.

ART PHOTOGRAPHS.—Mr. Blanchard has just issued a few very charming whole plate art studies, consisting of Italian peasants and other subjects. The especial object is to illustrate the quality of negative produced by his carte de visite collodion with simple iron development without intensifying. Photographically they are perfect, round, delicate, full of gradation and yet admirably vigorous. They also exhibit fine artistic feeling. The pose, expression arrangement of accessories, &c., all are good.

OBITUARY.—It is with deep regret that we announce the sudden death of Mr. Bland, of the firm of Bland and Co. (formerly Bland and Long). He had been indisposed for a few days, but not seriously, and on Wednesday, the 23rd, was suddenly taken worse and died. He had been for many years connected with the business of a philosophical instrument maker and dealer in photographic apparatus, in which position he was highly respected, whilst his personal qualities, his constant courtesy, his kindly and urbane manners, won the esteem and regard of all who came in contact with him.

To Correspondents.

W. G.—The only method of producing enamel or burnt-in photographs which has been patented in this country is that of M. Joubert, which consists in coating the plate with a mixture of a chromic salt, albumen, and honey, and after exposure under a transparent positive applying vitreous colours in powder, and burning in the usual muffle furnace. We believe you are quite at liberty to practice the other methods which you indicate.

D. JONSON.—We have not had much experience as to the keeping qualities of simply washed and dried plates. Tannin plates carefully prepared will, we believe, keep some months; and collodio-albumen plates, especially if they receive a thorough final washing, and then a coat of a solution of gallic acid, will also keep many months. The real action of a preservative coating of some organic substance in dry plates is not well ascertained. Some maintain that its action is chemical; others, headed by Dr. Hill Norris, contend that it is merely mechanical, and simply serves to keep open the pores of the film. We do not know of any method of intensifying dry plates better than the use of pyro and silver, preceded, if necessary, with a wash of a solution of iodine.

ST. DENNIS.—The album and other views issued by Mr. Wilson are published by Marion and Co., of Soho Square.

NEMO.—We do not see that any advantage will be gained in using a nitrate bath of 100 grains to the ounce for dry plates. Where bromized collodion only is used, and in large proportion a strong bath is desirable, but not nearly so strong as you mention. You cannot with advantage use a larger portion of iodine than the film will hold with convenience when formed into iodide of silver. If you use much more than is commonly used you will be troubled with all the results which follow over-iodizing.

P. J.—The kind of fogging which you describe, and which may be rubbed off the image, leaving it very weak, is probably caused by a want of relation between your nitrate bath and developer. The latter is probably new, somewhat strong, and without a large proportion of acid. Your nitrate bath is probably weak, and the image is chiefly formed on the surface of the film. Your best remedy will be to increase the proportion of acid in your developer. The yellow glass in your dark-room becoming too pale

would cause fogging, but the fogging from diffused light does not rub off the image easily.

C. C.—The quantity of water should have been stated in ounces.

Z. φ.—We cannot state certainly the cause of the spots. They have very much the appearance of having been caused by splashes of some liquid at the back of the paper after it was sensitized.

J. R. N.—The last edition of Mr. Hardwich's "Manual of Photographic Chemistry" is the sixth. We have not seen any announcement of a new edition. It is not probable that any other edition will pass through Mr. Hardwich's hands. 2. Mr. Sutton's work on carbon printing gives all details of Mr. Pouncy's process, and of some others. There is no work describing all the methods of carbon printing which have been invented. 3. The remedy for the curling of card pictures in rolling is to use a roller of larger diameter. Or, if they are rolled face down on a steel plate, they will be less likely to curl. 4. *Humphrey's Journal* is an American Photographic Journal, published in New York. 5. If you suspect that your bath contains too much acid, neutralise it by adding a solution of bicarbonate of soda until a slight permanent precipitate is formed, and then try it. Sometimes it will work well without any addition of acid; if it does not you can add acid very cautiously until it works.

X. Y. Z.—There are various samples of collodion in the market which adhere well. We have found that which you are mixing—Blanchard's—to adhere very firmly to the glass.

D. W., Aberdeen.—The black colour which opticians produce on the polished part of their brass work is produced by what is termed in the trade "chemical bronze." We believe this is simply a preparation of chloride of platinum, but is generally bought by the optician ready for use, of the chemist. The brass work is first thoroughly cleansed, and then the solution is applied by means of a camel's-hair pencil. The recipe in "Hardwich's Manual," to which you refer, is for producing a dead black, and is wrong for that. The brass work should not be heated, as directed, or the contrary result to that indicated will follow. A lacquer, or spirit varnish, dries dead only when applied cold, and bright when applied with heat. We have not observed the cause of spots to which you refer. Your aim at perfect excellence is wise and right.

A. GRENET.—The back lenses of an ordinary portrait combination are arranged as follows:—The double convex lens is first placed in its cell, with the least convex side downwards; the ring is next placed upon it to preserve the proper separation; the other lens is then placed upon that concave side downwards, and the brass collar screwed in to retain them in position. They then present the effect of one very thick double convex lens.

E. E. D.—The best moist preservative which we know for keeping the plate fit for use for a few hours is that described in our pages by Mr. Blanchard, about twelve months ago, and also in our last PHOTOGRAPHIC NEWS ALMANAC.

J. H. C., 42.—There is no distinct work on producing photographic transparencies. Major Russell's work has a short chapter on producing them on tannin plates, and other works have chapters on the subject. A variety of copious articles on the subject have appeared in our pages. M. Bisson has not written on the subject we believe. We are uncertain as to when the work you inquire about will be ready; it is in preparation we believe.

CORNISH COURIER.—The use of a larger proportion of bromide in the collodion is one of the best sources of gradation in glass positives. And with a freely bromized collodion the bath may be freely acidified with nitric acid. With these, and a developer containing about 15 grains of protosulphate of iron, 15 minims of glacial acetic, and 2 minims of nitric acid, we do not see how you can fail, with proper lighting and exposure, to get good and well modelled glass positives. We do not believe that the use of methylated alcohol in the collodion will present any difficulty. We have produced many hundreds of glass positives as fine as ever we saw, with such collodion. We have experimented largely with methylated spirit, and have no reason to believe in the alleged evils.

AN OLD SUBSCRIBER wishes Mr. Bartholomew to state "why" he uses the sediment of chalk in his toning bath, seeing that the chloride of lime neutralizes any free acid, and the acetate of soda would bring about the necessary decomposition, and he quotes Mr. Sutton's statement that all additions beyond chloride of lime are useless or injurious. Pending Mr. Bartholomew's answer, we may remark that we first published a formula for a toning bath with chloride of gold and chloride of lime only, that of Mr. Lacy. In many hands it gives exceedingly fine results. But it has certain disadvantages. If used within a week after it is mixed it generally gives meanness. Again this difficulty arises, whilst chloride of lime is sufficiently alkaline to neutralize any free acid, it sometimes happens with some samples of chloride of gold, that if sufficient chloride of lime be used to neutralize it, too much free chlorine is added at the same time. To produce the best results the proportion of chloride of lime must be kept within proper limits, and hence the utility of a salt like carbonate of lime to complete the neutralizing process where it is necessary, and which will be simply innocuous when it is not needed to neutralize any free acid.

W.—We think it is probable that the collodion being new and horny, or repellent, probably causes the mottling. The use of a more permeable collodion, or of a weaker tannin solution, or washing after applying the tannin solution, may prevent the defect. We hope, in our next, to give Major Russell's opinion on the subject.

Several Correspondents in our next.

ALKALINE DEVELOPMENT—MACKEREL MARKS ON TANNIN PLATES.

The principle of alkaline development for dry plates appears to be gaining general recognition. Nevertheless, with it, as with several other not perfectly understood processes in photography, there is much discrepancy in the experience of different operators. The results, as described by some, are equal to those produced by the wet process and with an equally short exposure; whilst with others spots, fog, and rotten films, are the invariable followers of an alkali in the developer. Others again, not failing like the last, nor gaining results equal in rapidity to wet collodion, like the first, find that a decided diminution in exposure, and a facility in successful development, are obtained by the judicious use of ammonia or soda in the developing solution. Amongst our recent correspondents we have illustrations of the two last classes, and a recent article in the *Photographic Notes* speaks of results similar to those referred to in the first class. Our own experience in this direction has not been very extended, but it has been tolerably successful. We have succeeded in obtaining clean, rapid, and satisfactory results, but not equal to those from wet collodion and iron development. Before speaking of our own experiments we will make a brief extract from one of the communications we have received on the subject. After referring to his failure to obtain good results with any moderate exposure, on tannin plates prepared with simply iodized collodion, our correspondent, signing "Delta," says:—

It has occurred to me, that in the various references to the origination of alkaline development, one name has been very singularly omitted, and as photographers are much indebted to the owner of that name for many valuable suggestions in your pages, it appears to me that this omission ought to be rectified. I refer to Mr. Bartholomew.

In the *PHOTOGRAPHIC NEWS*, for January 3rd, 1862, I find in an article, by Mr. Bartholomew, the following suggestive remarks, in describing three new dry processes:—"The third formula involves the recognition in dry plate photography of a principle which has hitherto not been noticed. It occurred to me that if, in the wet collodion process, we require free nitrate of silver, acid reaction, and no organic matter; so, probably, in the dry collodion process, we require no free nitrate of silver, alkaline reaction, and organic matter." He then proceeds to describe a process in which gelatine is used as a preservative, with a solution of carbonate of soda either added to the solution or applied afterwards; and he adds, that plates so prepared are equal in sensitiveness to those prepared by the wet process.

Now, sir, it appears to me that here is the germ of the modern improvement in development very distinctly set forth, and that to Mr. Bartholomew is due the credit of first proposing the heterodox notion that alkaline conditions might be advantageous in dry plate photography. It is the more important that this recognition be made, as I see, in the *PHOTOGRAPHIC NOTES*, that Mr. Sutton, who has become a convert to this mode of development, as he did to the use of bromides, has recently propounded, as a new preservative, a mixture of albumen, honey, and carbonate of soda, a mixture which,

although not the same, is uncommonly like Mr. Bartholomew's, and which, at the time, I believe, Mr. Sutton pool-pooled.
